

EXTREME LOW POWER RTC WITH I2C,

32-bit UNIX time counter, 43 bytes EEPROM, Battery Switchover and Trickle Charger

DESCRIPTION

The EM3028 engineered using the in-house analog low power (ALP) technology provides unmatched true ultra-low current consumption of typically 45nA while running on a standard 32'768 Hz tuning fork crystal. Thus allowing several hours of backup supply using cost effective MLCC capacitors.

It provides full RTC function with programmable counters, alarm, selectable interrupt and clock output functions and also a 32-bit UNIX Time counter.

The internal EEPROM memory hosts all configuration settings and allows for additional 43 bytes of user memory.

All addresses and data are transferred over an I2C-bus interface for communication with a host controller.

It is available in a TSSOP14 plastic package or as a module combining the 32 kHz Crystal with the RTC IC in an ultrasmall, hermetically sealed C7 SMD package, factory calibrated to an initial accuracy of \pm 1ppm.

FEATURES

- I Extreme low power consumption: 45 nA @ 3 V.
- I Wide operating voltage range: 1.2 V to 5.5 V.
- I Built-in tuning Fork crystal at 32'768 Hz
- I Time accuracy: possible to calibrate to ±1 ppm @ 25°C
- I Non-volatile configuration settings with user programmable offset value.
- I Configuration stored in EEPROM and mirrored in RAM
- I Password protection to secure configuration registers
- I Backup Switch and Trickle Charger function.
- I Provides year, month, date, weekday, hours, minutes and seconds.
- I Automatic leap year correction; 2000 to 2099
- I 32 bit UNIX time counter.
- I Timer, alarm and external event functions with time stamp
- I Clock output: 32.768 kHz, 8192 Hz, 1024 Hz, 64 Hz, 32Hz, 1 Hz.
- I 43 bytes non-volatile user memory, 2 bytes user RAM.
- I I²C-bus interface: 400 kHz.
- I Package: TSSOP14, 100% Pb-free, RoHS-compliant
- I Also available in ultra-small SMD C7 package, factory calibrated and including the 32kHz crystal, part number EM3028-C7

APPLICATIONS

- I loT
- I Wearable systems
- I Multi-Solar cell platforms
- I Beacons and wireless sensor networks
- I Industrial and environmental monitoring
- I Battery operated platform

1. PRODUCT DESCRIPTION

The EM3028 is an extreme-low power CMOS based Real-Time with external 32.768 kHz Crystal. The oscillator circuit does not require any external resistors or capacitors to operate. Refer to **5.4 Oscillator Characteristics** for the external crystal parameters.

It includes an Automatic Backup switchover function with a Trickle charger where the interrupt output on nINT pin is also working in VBACKUP Power state. The clock output on FOUT pin can be enabled normally via command over interface or can be interrupt driven and synchronized clock output enable/disable on FOUT pin can be freely selected. The configuration registers are stored permanently in non-volatile EEPROM and mirrored in RAM in order that the RTC is still configured correctly even after power down. For safety against inadvertent overwriting the time registers and configuration registers can be protected by a User Programmable Password. Additionally, there is an OscOffset value customer use for aging correction.

The EM3028 provides standard Clock & Calendar function including seconds, minutes, hours (12 or 24 h), weekdays, date, months, years (with leap year correction) and interrupt functions for the Periodic Countdown Timer, Periodic Time Update, Alarm, External Event, Automatic Backup Switchover and Power On Reset. All is accessible via I²C-bus (2-wire Interface). The interrupt functions and the Time Stamp of the External Event function are also working in VBACKUP Power state. Beside the standard RTC functions a 32-bit UNIX Time counter and 43 Bytes of non-volatile User Memory EEPROM and 2 Bytes of User RAM are provided. A further Byte can be used as User RAM when the Periodic Countdown Timer is not used (Timer Value register 0Ah) and a further Byte when the Alarm function is not used (Alarm register 07h).

1.1. BLOCK DIAGRAM

Figure 1-1 EM3028 Block Diagram

1.2. OPERATING MODES

The registers are accessed by selecting a register address and then performing read or write operations. Multiple reads or writes may be executed in a single access, with the address automatically incrementing after each byte. When address is automatically incremented, wrap around occurs from address 3Fh to address 00h (see Figure 1-2 Address register auto-increment). All registers are designed as addressable 8-bit registers despite the fact that not all registers and bits are implemented (reserved).

Figure 1-2 Address register auto-increment

1.2.1. DEVICE PROTECTION

Figure 1-3 Device Diode Protection Diagram

1.2.2. REGISTER ORGANIZATION

- RAM Registers at addresses 00h to 28h are accessed by selecting a register address and then performing read or write operations. Multiple reads or writes may be executed in a single access, with the address automatically incrementing after each byte.
- The Configuration Registers at addresses 2Bh and 30h to 37h are memorized in EEPROM and mirrored in RAM.
- There are 43 bytes of non-volatile user memory EEPROM at addresses 00h to 2Ah for general use.

The following tables summarize the function of each register.

REGISTER CONVENTIONS

The conventions in this table serve as a key for the register overview and individual register diagrams:

Convention (Conv.)	Description
R	Read only. Writing to this register has no effect.
W	Write only. Returns 0 when read.
R/WP	Read: Always readable. Write: Can be write-protected by password.
WP	Write only. It can be write-protected by password.
Prot.	Protected. Not readable, but normal address pointer incrementing.

1.2.3. REGISTER OVERVIEW

After reset, all registers are set according to Table in section Register Reset Values Summary.

Register Definitions; RAM, Address 00h to 3Fh:

Address	Function	Conv.	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

2Ch to 2Fh	EEPROM RESERVED	Prot.	RESERVED							
38h to 3Fh	EEPROM RESERVED	Prot.		RESERVED						

⁻ Bit not implemented. Will return a 0 when read.

2. HANDLING PROCEDURES

This device has built-in protection against high static voltages or electric fields; however, anti-static precautions must be taken as for any other CMOS component. Unless otherwise specified, proper operation can only occur when all terminal voltages are kept within the voltage range. Unused inputs must always be tied to a defined logic voltage level.

3. PIN DESCRIPTION

	PIN	I/O 7	ГҮРЕ	DESCRIPTION
NO.	NAME	DIRECTION	SUPPLY	
1	V_{DD}			Positive power supply
2	VBAckup			Battery Supply Voltage. When the backup switchover function is not needed, VBACKUP must be tied to Vss with a 10 k Ω resistor.
3	V _{SS}		V_{SS}	Ground
4	TESTEM	1	V_{DD}	Test input for factory test. Connect to Vss
5	Xtal_out	0		Oscillator output Wire length between quartz and package shall be minimized.
6	Xtal_in	I		Oscillator input Wire length between quartz and package shall be minimized.
7	SDA	I/O	V _{DD}	I ² C Serial Data Input-Output; open-drain; requires pull-up resistor. In VBACKUP Power state, the SDA pin is disabled (high impedance).
8	SCL	I	V_{DD}	I ² C Serial Clock Input; requires pull-up resistor. In VBACKUP Power state, the SCL pin is disabled.
9	nINT	0	V _{DD} or Vbackup	Interrupt Output; open-drain; active LOW; requires pull-up resistor; used to output Periodic Countdown Timer, Periodic Time Update, Alarm, External Event, Automatic Backup Switchover and Power On Reset Interrupt signals. Interrupt output also in VBACKUP Power state.
10	EVI	I	V _{DD} or V _{BACKUP}	External Event Input; used for interrupt generation, interrupt driven clock output and time stamp function. Remains active also in VBACKUP Power state. This pin should not be left floating.
11	FOUT	0	V_{DD}	Clock Output; push-pull; Normal and Interrupt driven clock output can be activated concurrently.
				 Normal clock output is controlled by the CLKOE bit. When CLKOE is set to 1 (default), the FOUT pin drives the square wave on the FOUT pin. When CLKOE bit is set to 0, the FOUT pin is LOW.
				 Interrupt driven clock output is controlled by an interrupt event. When CLKIE is set to 1 the occurrence of the interrupt selected in the Clock Interrupt Mask Register (12h) allows the square wave output on the FOUT pin. Writing 0 to CLKIE will disable new interrupts from driving square wave on FOUT. When CLKF flag is cleared, the FOUT pin is LOW.
				Depending of the settings in the XO field, the FOUT pin can drive the square wave of 32.768 kHz (default), 8192 Hz, 1024 Hz, 64 Hz, 32 Hz or 1 Hz, or the predefined periodic countdown timer interrupt. When XO field is 111 the FOUT pin is LOW.
				When CLKSY bit set to 1, the enabling and disabling of the clock output is synchronized. CLKSY has no effect on the timer interrupt signal.
				In VBACKUP Power state, the FOUT pin is LOW.

Electrostatic discharge to ANSI/ESDA/JEDEC JS-001 for HBM	-2000	+2000	V		
Latch-up testing, according to JESD78., Class I (room temperature), level A (100)	-100	+100	mA		

Table 2 Absolute maximum ratings

Stresses above these listed maximum ratings may cause permanent damages to the device. Exposure beyond specified operating conditions may affect device reliability or cause malfunction.

Warning: The device is not functional when exposed to light. When a non-packaged version is used, it is mandatory to protect the device from light.

5.2. OPERATING CONDITIONS

Oscillator start-up time at V _{DD} = 3.0 V	t start	(CLKOE = 1)		0.5	3	S
First refreshment time	trefr	(02::02 :)		66		ms

Table 5 Timing Characteristics

5.5.1. POWER ON

The following Figure describes the power on AC electrical characteristics for the FOUT pin. The clock output signal on FOUT pin is enabled by the CLKOE bit (EEPROM 35h), see also **Use of the Configuration EEPROM WITH RAM MIRROR Registers.**

Power On AC Electrical Characteristics:

- 1 Regardless of the state of bit CLKOE, the FOUT pin is driving the frequency selected by the FD field (EEPROM 35h) after the start-up time tSTART = 0.5 s (FOUT can also be LOW, when selecting FD = 111).
- ② If the CLKOE bit (EEPROM 35h) was set to 0 beforehand (in EEPROM), the CLKOE bit in the RAM is set to 0 after the start-up time tSTART = 0.5 s and the first refreshment time t_{REFR} = ~66 ms, and the FOUT signal goes LOW. Or else, if the CLKOE bit (EEPROM 35h) was set to 1 beforehand (in EEPROM), the CLKOE bit in the RAM is set to 1 after the start-up time tSTART = 0.5 s and the first refreshment time t_{REFR} = ~66 ms, and the FOUT pin is driving the frequency selected by the FD field.

Figure 5-3 Power On Timing Diagram

5.5.2. I²C-BUS CHARACTERISTICS

The following Figure and Table describe the I²C AC electrical parameters.

I²C AC Parameter Definitions:

Figure 5-4 I²C BUS Timing Diagram

Table 6 5 I²C Timing Characteristics

Caution.

When accessing the EM3028, all communication from transmitting the Start condition to transmitting the Stop condition after access should be completed within 950 ms.

If such communication requires 950 ms or longer, the I²C bus interface is reset by the internal bus timeout function.

6. PRODUCT CONFIGURATION

6.1. CLOCK REGISTERS

00h – Seconds. This register holds the count of seconds, in two binary coded decimal (BCD) digits. Values will be from 00 to 59. Read: Always readable. Write: Can be write-protected by password.

on so to connection where to addition times bear to time protected by passivera.											
Address	Function	Conv.	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

Bit	Symbol		Value			De	escription			
7	0		0	Read only. Always 0.						
6:0	Minutes		00 to 59	Holds the count of minutes, coded in BCD format.						

Table 8 Minutes (0x01h).

02h – Hours. This register holds the count of hours, in two binary coded decimal (BCD) digits. If the 12_24 bit is cleared (default) (see **Configuration Registers**, 10h – Control 2) the values will be from 0 to 23. If the 12_24 bit is set, the hour values will range from 1 to 12 and the AMPM bit will be 0 for AM hours and 1 for PM hours. Read: Always readable. Write: Can be write-protected by password.

Address	Function	Conv.	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

		1	Disabled – Default value
6	0	0	Read only. Always 0.
5:0	Date Alarm	01 to 31	Holds the alarm value for the date, coded in BCD format. The Reset value 00 after POR has to be replaced by a valid value (01 to 31).

Table 16 Weekday/Date Alarm (0x09h).

6.4. PERIODIC COUNTDOWN TIMER CONTROL REGISTERS

0Ah – Timer Value 0. This register is used to set the lower 8 bits of the Timer Value (preset value) for the Periodic Countdown Timer. This value will be reloaded into the Countdown Timer when it reaches zero if the TRPT bit is 1. This allows for periodic timer interrupts (see calculation below). Read: Always readable. Write: Can be write-protected by password.

Address	Function	Conv.	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
0Ah	Timer Value 0	R/WP	128	64	32	16	8	4	2	1

Table 19 Timer Status 0 (0x0Ch).

0Dh – Timer Status 1 shadow. This register holds the upper 4 bits of the current value of the Periodic Countdown Timer. It is read only. Writing to this register has no effect.

Address	Function	Conv.	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
0Dh	Timer Status 1	R	0	0	0	0	2048	1024	512	256
UDN	Reset		0	0	0	0	0	0	0	0
Bit	Symbol		Value			D	escription			
7:4	0		0	Read only. Al	ways 0.					

Table 20 Timer Status 1 shadow (0x0Dh).

When TE bit is set to 1, reading the Timer Status 0 value updates the Timer Status 1 shadow register. Reading Timer Status 1 will return the Timer Status 1 shadow register value, memorized during Timer Status 0 read. When a 0 is written to the TE bit, the Timer Status 0 and Timer Status 1 registers store the last updated value.

6.5. CONFIGURATION REGISTERS

0Eh – Status. This register is used to detect the occurrence of various interrupt events and reliability problems in internal data. Read: Always readable. Write: Can be write-protected by password.

Status		Function	Conv.	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
Bit Symbol Value Description	051	Status	R/WP	EEbusy	CLKF	BSF	UF	TF	AF	EVF	PORF
EEPROM Memory Busy Status Bit - (Read Only) (see EEPROM READ/WRITE)	UEN	Reset		1 → 0	0	0	0	0	0	Х	1
EEPROM Memory Busy Status Bit - (Read Only) (see EEPROM READ/WRITE)											
The transfer is finished. Indicates that the EEPROM is currently handling a read or write request and will ignore any further commands until the current one is finished. At power up a refirsh is automatically generated. The time of this first refreshment is –66 ms. After the refreshment is finished. Ebusy is olerared to 0 but organized to 10 but forequency output will stop depending on CLKSY and FOUT settings. It set to 0 beforehand, indicates the occurrence of an interrupt driven clock output on FOUT pin. The value 1 is retained until a 0 is written by the user.	Bit	Symbol		Value				Description			
Indicates that the EEPROM is currently handling a read or write request and will ignore any further commands until the current one is finished At power up a refresh is automatically generated. The time of this first refreshment is ~66				EEPROM N	Memory Busy	y Status Bit	- (Read Only)	(see EEPRO I	M READ/WF	RITE)	
1 any further commands until the current one is finished. At power up a refresh is automatically generated. The time of this first refreshment is ~66 ms. After the refreshment is finished, EEbusy is cleared to 0 automatically. Clock Output Interrupt Flag (see Programmable Clock Output) 0 No event detected. When cleared to 0 the frequency output will stop depending on CLKSY and FOUT settings. 1 If set to 0 beforehand, indicates the occurrence of an interrupt driven clock output on FOUT pin. The value 1 is retained until a 0 is written by the user. Backup Switch Flag (see AUTOMATIC BACKUP Switchover Function) 0 No backup switchover detected. At power up (POR) this flag is automatically cleared to 0 When the backup switchover function is disabled (PM field ~ 00) BSF is always logic 0. 1 If set to 0 beforehand, indicates that a switchover from an power V ₇₀ , to Vaccyun has occurred. The value 1 can be cleared by writing a 0 to the bit if RTC module is in VDD 1 Power state. Caution: The EVF flag is also set by an event of the Backup Switchover function when bits TSS and TSE are set to 1. Periodic Time Update Flag (see Periodic Time Update Interrupt Function) 1 If set to 0 beforehand, indicates the occurrence of a Periodic Time Update Interrupt event. The value 1 is retained until a 0 is written by the user. Periodic Countdown Timer Flag (see Periodic Countdown Timer Interrupt Function) 1 No event detected. 1 If set to 0 beforehand, indicates the occurrence of a Periodic Countdown Timer Interrupt event. The value 1 is retained until a 0 is written by the user. Alarm Flag (see Alarm Interrupt Function) 2 AF 1 EVF 2 AF 1 EVF 1 EVF 1 EVF 1 EVF (bedeativ Auto depends on the voltage on the EVI pin and has to be cleared by writing a 0 to the bit. At POR, EVF = 0, no LOW level was detected on EVI pin. 6.6. EVENT CONTROL REGISTER

13h – Event Control. This register controls the event detection on the EVI pin. Depending of the EHL bit a high or a low signal can be detected. Moreover a digital glitch filtering can be applied to the EVI signal by selecting a sampling period in the ET field. Furthermore this register holds control functions for the Time Stamp data. And the switching over to VBACKUP Power state can be selected as source for an event. Read: Always readable. Write: Can be write-protected by password.

Symbol Value Description	Address	Function	Conv.	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

6.7. TIME STAMP REGISTERS

14h – Count TS. This register contains the number of occurrences of the corresponding event in standard binary format. The values range from 0 to 255. It is read only. Writing to this register has no effect.

Address	Function	Conv.	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
1.4h	Count TS	R	128	64	32	16	8	4	2	1
14h	Reset 0		0	0	0	0	0	0	0	

Bit	Symbol	Value	Description
7:0	Count TS	0 to 255	Number of occurrences of the corresponding event, coded in binary. In case of an overflow the counter starts again with 00h When bit TSE = 0, the counter stops counting events. When bit TSE = 1, the counter is increased when event occurs. The counter Count TS is always working, independent of the settings of the overwrite bit TSOW. The Count TS register is cleared to 00h when a 1 is written to the reset bit TSR (see TIME STAMP Function)

Table 27 Count TS (0x14h).

15h – Seconds TS. This register holds a recorded Time Stamp of the Seconds register, in two binary coded decimal (BCD) digits. The values are from 00 to 59. It is read only. Writing to this register has no effect.

Address	Function	Conv.	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
15h	Seconds TS	R	0	40	20	10	8	4	2	1
	Reset		0	0	0	0	0	0	0	0

Bit	Symbol	Value	Description
7	0	0	Read only. Always 0.
6:0	Seconds TS		Holds a recorded Time Stamp of the Seconds register, coded in BCD format. When enabled (bit TSE = 1), Depending on the setting of the TSOW bit it contains the time stamp of the first or last occurred event. The Seconds TS register is cleared to 00h when a 1 is written to the reset bit TSR.

Table 28 Seconds TS (0x15h).

16h – Minutes TS. This register holds a recorded Time Stamp of the Minutes register, in two binary coded decimal (BCD) digits. The values are from 00 to 59. It is read only. Writing to this register has no effect.

Address	Function	Conv.	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
16h	Minutes TS	R	0	40	20	10	8	4	2	1
	Reset		0	0	0	0	0	0	0	0

Bit	Symbol	Value	Description
7	0	0	Read only. Always 0.
6:0	Minutes TS	00 to 59	Holds a recorded Time Stamp of the Minutes register, coded in BCD format. When enabled (bit TSE = 1), Depending on the setting of the TSOW bit it contains the time stamp of the first or last occurred event. The Minutes TS register is cleared to 00h when a 1 is written to the reset bit TSR.

Table 29 Minutes TS (0x16h).

17h – Hours TS. This register holds a recorded Time Stamp of the Hours register, in two binary coded decimal (BCD) digits. If the 12_24 bit is cleared (default) (see **Configuration Registers**, 10h – Control 2) the values will be from 0 to 23. If the 12_24 bit is set, the hour values will range from 1 to 12 and the AMPM bit will be 0 for AM hours and 1 for PM hours. It is read only. Writing to this register has no effect.

Address	Function		Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
17h	Hours TS (24 hour mode) – default value Hours TS (12 hour mode)		R o	0	20	10	8	4	2	1
					AMPM	10	8	4	2	1
	Reset	0	0	0	0	0	0	0	0	

Hours TS (24 hour mode) – default value		
Bit	Symbol	Value	Description
7:6	0	0	Read only. Always 0.
5:0	Hours TS (24 hour mode) – default value	0 to 23	Holds a recorded Time Stamp of the Hours register, coded in BCD format. When enabled (bit TSE = 1), Depending on the setting of the TSOW bit it contains the time stamp of the first or last occurred event. The Hours TS register is cleared to 00h when a 1 is written to the reset bit TSR.

Hours TS	(12 hour mode)		
Bit	Symbol	Value	Description
7:6	0	0	Read only. Always 0.
5	AMPM	0	AM hours, from the recorded Time Stamp of the Hours register.
5	AWFW	1	PM hours, from the recorded Time Stamp of the Hours register.
4:0	Hours TS (12 hour mode)	1 to 12	Holds a recorded Time Stamp of the Hours register, coded in BCD format. When enabled (bit TSE = 1), Depending on the setting of the TSOW bit it contains the time stamp of the first or last occurred event. The Hours TS register is cleared to 00h when a 1 is written to the reset bit TSR.

Table 30 Hours TS (0x17h).

18h – Date TS. This register holds a recorded Time Stamp of the Date register, in two binary coded decimal (BCD) digits. The values will range from 01 to 31. It is read only. Writing to this register has no effect.

18h Date TS R o o 20 10 8 4 2 Reset 0	Address	Function	Conv.	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
	10h	Date TS		0	0	20	10	8	4	2	1
	1011	Reset		0	0	0	0	0	0	0	0

Bit	Symbol	Value	Description
7:6	0	0	Read only. Always 0.
5:0	Date TS	01 to 31	Holds a recorded Time Stamp of the Date register, coded in BCD format. When enabled (bit TSE = 1), Depending on the setting of the TSOW bit it contains the time stamp of the first or last occurred event. The Date TS register is cleared to 00h when a 1 is written to the reset bit TSR. After POR or when reset with bit TSR and when a Time Stamp is recorded, the value 00 will be automatically replaced by a valid value (01 to 31).

Table 31 Date TS (0x18h).

19h - Month TS. This register holds a recorded Time Stamp of the Month register, in two binary coded decimal (BCD) digits. The values will range from 01 to 12. It is read only. Writing to this register has no effect.

Address	Function	Conv.	Bit 7	Bit 6	Bit 6 Bit 5 Bit 4 Bit 3 Bit 2 Bit 1					
19h	Month TS	R	0	0	0	10	8	4	2	1
1911	Reset 0			0	0	0	0	0	0	0
Bit	Symbol		Value	Description						
7:5	0		0	Read only. Always 0.						

Bit	Symbol	Value	Description
7:5	0	0	Read only. Always 0.
4:0	Month TS	01 to 12	Holds a recorded Time Stamp of the Month register, coded in BCD format. When enabled (bit TSE = 1), Depending on the setting of the TSOW bit it contains the time stamp of the first or last occurred event. The Month TS register is cleared to 00h when a 1 is written to the reset bit TSR. After POR or when reset with bit TSR and when a Time Stamp is recorded, the value 00 will be automatically replaced by a valid value (01 to 12).

Table 32 Month TS (0x19h).

1Ah – Year TS. This register holds a recorded Time Stamp of the Year register, in two binary coded decimal (BCD) digits. Values will range from 00 to 99. It is read only. Writing to this register has no effect.

Address	Function	Conv.	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
4.0 -	Year TS	R	80	40	20	10	8	4	2	1
1Ah	Reset		0	0	0	0	0	0	0	0

Bit	Symbol	Value	Description
7:0	Year TS	00 to 99	Holds a recorded Time Stamp of the Year register, coded in BCD format. When enabled (bit TSE = 1), Depending on the setting of the TSOW bit it contains the time stamp of the first or last occurred event. The Year TS register is cleared to 00h when a 1 is written to the reset bit TSR.

Table 33 Year TS (0x1Ah).

6.8. UNIX TIME REGISTERS

The UNIX Time counter is a 32-bit counter with the value in binary format. The counter will roll-over to 00000000h when reaching FFFFFFFh. The 4 counter registers are fully readable and writable. The counter source clock is the digitally tuned 1 Hz clock frequency. The UNIX Time counter increment is inhibited during I²C write access to the 4 UNIX Time registers to allow coherent data values (see **Setting and Reading the Time**). Read: Always readable. Write: Can be write-protected by password.

1Bh - UNIX Time 0. Bit 0 to 7 from 32-bit UNIX Time counter.

Table 39 User RAM 2 (0x20h)

6.10. PASSWORD REGISTERS

After a Power up and the first refreshment of ~66 ms, the PW 0 to PW 3 registers are reset to 00h.

When enabled by writing 255 into the EEPROM Password Enable register EEPWE (EEPROM 30h), the Password registers are used to be written with the 32-Bit Password necessary to be able to write into all writable registers (for time and configuration registers). This 32-Bit Password is compared to the 32 bits stored in the EEPROM Password registers EEPW 0 to EEPW 3 (EEPROM 31h to 34h) (see **EEPROM Password Registers**).

21h - Password 0. Bit 0 to 7 from 32-bit Password. Write only. Returns 0 when read.

Table 45 EEPROM Data (0x26h)

27h –EEPROM Commands. This register must be written with specific values, in order to read or write all (readable/writeable) configuration registers or to read or write from/to a single EEPROM Memory byte. Before using this commands, the automatic refresh function has to be disabled (EERD = 1) and the busy status bit EEbusy has to indicate, that the last transfer has been finished (EEbusy = 0). Before entering the command 11h, 12h, 21h or 22h, EEcmd has to be written with 00h. Write only. It can be write-protected by password.

User EEPROM, default values on delivery:

User EEPROM (43 Bytes) = 00h

Manufacturer EEPROM, Address 2Ch to 2Fh and 38h to 3Fh, default values on delivery:

EEPROM RESERVED = XXh (protected)

7. DETAILED FUNCTIONAL DESCRIPTION

7.1. POWER ON RESET (POR)

The power on reset (POR) is generated at start-up (see POWER ON). All RAM registers including the Counter Registers are initialized to their reset values and the Configuration EEPROM registers with the RAM mirror registers are set to their preset default values. At power up a refresh of the RAM mirror values by the values in the Configuration EEPROM is automatically generated. The time of this first refreshment is ~66 ms. The EEbusy bit in the Status register (0Eh) can be used to monitor the status of the refreshment (see Register Reset Values Summary).

The Power On Reset Flag PORF indicates the occurrence of a voltage drop of the internal power supply voltage below V_{POR} threshold needed to cause the generation of the device POR. A PORF value of 1 indicates that the voltage had dropped below the threshold level V_{POR} and that the time information is corrupted. The value 1 is retained until a 0 is written by the user.

When PORIE bit (EEPROM 35h) is set and the PORF flag was cleared beforehand, an interrupt signal on nINT pin can be generated when a Power On Reset occurs (see **POWER ON RESET Interrupt Function**).

7.2. AUTOMATIC BACKUP SWITCHOVER FUNCTION

Basic Hardware Definitions:

- The EM3028 has two power supply pins.
 - o V_{DD} is the main power supply input pin.
 - V_{BACKUP} is the backup power supply input pin.
- V_{TH:LSM} is the backup switchover threshold voltage. The typical value is 2.0 V.
- A debounce logic provides a 122 μs 183 μs debounce time t_{DEB}, which will filter V_{DD} oscillation when the backup switchover will switch back from V_{BACKUP} to V_{DD}.
- The FEDE bit (EEPROM 37h) should always be set to 1, so that Fast Edge Detection (≥ 7 V/ms) is always enabled. Default value on delivery

Switchover Modes:

The EM3028 has four backup switchover modes. The desired mode can be selected by the BSM field in the Configuration EEPROM, see **EEPROM BACKUP Register**:

- BSM = 00. Backup switchover disabled (default value on delivery), see SWITCHOVER Disabled.
- BSM = 01. Direct Switching Mode (DSM): when $V_{DD} < V_{BACKUP}$, switchover occurs from V_{DD} to V_{BACKUP} without requiring V_{DD} to drop below $V_{TH:LSM}$, see **Direct Switching Mode (DSM)**.
- BSM = 10. Standby mode: when V_{DD} < V_{BACKUP} (backup battery charged, no V_{DD}), the device enters the standby mode and draw any current from the backup source, see **STANDBY MODE**.
- BSM = 11. Level Switching Mode (LSM): when V_{DD} < V_{BACKUP} AND V_{DD} < V_{TH:LSM} (AND V_{BACKUP} > V_{TH:LSM}), switchover occurs from V_{DD} to V_{BACKUP}, see Level Switching Mode (LSM).

Function Overview:

When a valid backup switchover condition occurs (direct or level switching mode) and the internal power supply switches to the V_{BACKUP} voltage (VBACKUP Power state) the following sequence applies:

- The Backup Switch Flag BSF is set and, if BSIE bit is 1 (EEPROM 37h), an interrupt will be generated on nINT pin and remains as long as BSF is not cleared to 0. If BSIE is 0 no interrupt will be generated (see Automatic BACKUP Switchover Interrupt Function).
- The I²C-bus interface is automatically disabled (high impedance) and reset.
- EVI input remains active for interrupt generation, interrupt driven clock output and time stamp function
- FOUT pin is held LOW during VBACKUP Power state.
- The interrupt output pin nINT remains active in VBACKUP Power state for any previously configured interrupt condition.
- Going into VBACKUP Power state can be used as a time stamp condition (see TIME STAMP Function).
- The backup switchover condition can also be used to enable the clock output on FOUT pin automatically, when again in VDD Power state (see **Automatic BACKUP Switchover Interrupt Function**).

The Backup Switch Flag BSF can be cleared using the I²C-bus interface as soon as the circuit resumes from VBACKUP Power state and switched back to V_{DD}.

Note: After the device has switched back from VBACKUP Power state to VDD Power state the I²C interface has to be reinitialized by sending a STOP followed by a START (see alsoI2C-BUS in Switchover Condition).

7.2.1. SWITCHOVER DISABLED

The automatic backup switchover function is disabled when the BSM field (EEPROM 37h) is set to 00 (default value on delivery). Used when only one power supply is available.

- The power supply is applied on V_{DD} pin.
- V_{BACKUP} pin must be tied to V_{SS} with a 10 k Ω resistor.
- The battery flag BSF is always logic 0.

7.2.2. DIRECT SWITCHING MODE (DSM)

This mode is selected with BSM = 01 (EEPROM 37h).

- If $V_{DD} > V_{BACKUP}$ the internal power supply is V_{DD} .
- If V_{DD} < V_{BACKUP} the internal power supply is V_{BACKUP}.

The Direct Switching Mode is useful in systems where V_{DD} is higher than V_{BACKUP} at all times (for example, $V_{DD} = 5.0$ V, $V_{BACKUP} = 3.5$ V). If the V_{DD} and V_{BACKUP} values are similar (for example, $V_{DD} = 3.3$ V, $V_{BACKUP} \ge 3.0$ V), the Direct Switching Mode is not recommended.

In Direct Switching Mode, the power consumption is reduced compared to the Level Switching Mode (LSM) because the monitoring of V_{BACKUP} and V_{TH:LSM} is not performed (typical I_{VDD:DIRECT} = 95 nA).

Note that the circuit needs in worst case 2 ms to react when the mode is changed from Standby Mode or Backup Switchover Disabled to DSM.

Backup switchover in Direct Switching Mode and with Backup Switchover Interrupt enabled with BSIE = 1 (EEPROM 37h):

Figure 7-1 Direct Switching Mode

7.2.3. STANDBY MODE

When the device is first powered up from the backup supply (V_{BACKUP}) but without a main supply (V_{DD}), the device automatically enters the Standby Mode. In Standby Mode the device does not draw any power from the backup source until the device is powered up from the main power supply V_{DD} .

It is also possible to enter into Standby Mode when the device is already supplied by the main power supply V_{DD} and a backup supply V_{BACKUP} is connected. To enter the Standby Mode, the BSM field (EEPROM 37h) has to be set logic 10. Then the main power supply V_{DD} must be removed. As a result of it, the device enters the Standby Mode and does not draw any current from the backup supply before it is powered up again from main supply V_{DD} and set to a switchover mode.

7.2.4. LEVEL SWITCHING MODE (LSM)

This mode is selected with BSM = 11 (EEPROM 37h).

- If V_{DD} > V_{BACKUP} OR V_{DD} > V_{TH:LSM}, the internal power supply is V_{DD}.
- If V_{DD} < V_{BACKUP} AND V_{DD} < V_{TH:LSM} (AND V_{BACKUP} > V_{TH:LSM}), the internal power supply is V_{BACKUP}.

In Level Switching Mode, the power consumption is increased compared to the Direct Switching Mode (DSM) because of the monitoring of V_{BACKUP} and $V_{TH:LSM}$ (typical $I_{VDD:LEVEL} = 115$ nA). See also typical characteristics in level switching mode in section **Electrical Characteristics**.

Note that the circuit needs in worst case 15.625 ms to react when the mode is changed from Standby Mode or Backup Switchover Disabled to LSM.

Backup switchover in Level Switching Mode and with Backup Switchover Interrupt enabled with BSIE = 1 (EEPROM 37h):

Figure 7-2 Level Switching Mode

7.3. TRICKLE CHARGER

The device supporting the V_{BACKUP} pin include a trickle charging circuit which allows a battery or supercapacitor connected to the V_{BACKUP} pin to be charged from the power supply connected to the V_{DD} pin. The circuit of the Trickle Charger is shown in the following Figure. The Trickle Charger is enabled with bit TCE (EEPROM 37h). The series current limiting resistor is selected by the TCR field (EEPROM 37h) as shown in the Figure (default value on delivery is 1 k Ω). A schottky diode, with a typical voltage drop of 0.25 V, is inserted in the charging path.

Trickle Charger:

Figure 7-3 Trickle Charger configuration

The trickle charger is disabled when the device is in VBACKUP Power state.

7.4. PROGRAMMABLE CLOCK OUTPUT

Six different frequencies or the countdown timer interrupt signal can be output on FOUT pin, the signal selection is done in the FD field (EEPROM 35h).

- 32.768 kHz, direct from Xtal oscillator, not tuned.
- 8192 Hz, 1024 Hz, 64 Hz, 32 Hz, 1 Hz; divided Xtal oscillator frequencies, digitally tuned according to the oscillator offset value EEOffset (EEPROM 36h and 37h).
- Timer interrupt is controlled by the Countdown Timer Control Registers and the Control 1 register.

The initial original clock signal (32.768 kHz) is initiated for switching on/off at his negative edge, a subsequently selected clock signal is taking over on his negative edge by controlling bits CLKF, CLKOE and FD field, in-between FOUT is tied to V_{SS} .

FOUT is tied to V_{SS} in VBACKUP Power state independent of the FOUT configuration settings.

The frequency output can be controlled directly via the I²C-bus interface commands (normal operation) or can be interrupt driven to allow waking up an external system by supplying a clock.

At POR the synchronization function is active since the bit CLKSY is set to 1 (default), the 32.768 kHz frequency is output to FOUT pin since the bit CLKOE is set to 1 (default) and FD field is set to 000 (default). Hint: These are the default values on delivery, stored in the Configuration EEPROM with RAM mirror. To customize these POR values, the user can change the values in the Configuration EEPROM.

7.4.1. FOUT FREQUENCY SELECTION

A programmable square wave is available at pin FOUT. Operation is controlled by the FD field (EEPROM 35h). Frequencies from 32.768 kHz (Default value on delivery) to 1 Hz and countdown timer interrupt can be generated for use as a system clock, microcontroller clock, input to a charge pump, or for calibration of the crystal oscillator.

Pin FOUT is a push-pull output that is enabled at power on (Default value on delivery). FOUT can be disabled by setting CLKOE bit to 0 or FD field to 111. When disabled, the FOUT pin is LOW.

The RESET bit function can affect the FOUT signal depending on the selected frequency. When 1 is written to the RESET bit and the FOUT is enabled, the FOUT pin goes LOW for the frequencies 1024 Hz to 1 Hz (for more details, see **RESET bit Function**).

FOUT Frequency Selection:

<u>i i requente c</u>		
FD	FOUT Frequency Selection	When 1 is written to the RESET bit
000	32.768 kHz –Default value on delivery	No effect
001	8192 Hz ⁽¹⁾	No effect
010	1024 Hz ⁽¹⁾	FOUT goes LOW
011	64 Hz ⁽¹⁾	FOUT goes LOW
100	32 Hz ⁽¹⁾	FOUT goes LOW
101	1 Hz ⁽¹⁾	FOUT goes LOW
110	Predefined periodic countdown timer interrupt (1) (2)	FOUT goes LOW
111	FOUT = LOW	No effect

^{(1) 8192} Hz to 1 Hz clock pulses and the timer interrupt pulses can be affected by correction pulses (see **Frequency OFFSET Correction**).

7.4.2. NORMAL CLOCK OUTPUT

Writing bit CLKOE to 1 will drive the selected frequency on FOUT, writing CLKOE to 0 will clear the selected frequency on FOUT.

7.4.3. INTERRUPT CONTROLLED CLOCK OUTPUT

Writing 1 to CLKIE the occurrence of the selected interrupt condition allows frequency output on FOUT. This function allows waking up an external system by outputting a clock.

Writing 0 to CLKIE will disable new interrupts from driving frequencies on FOUT, but if there is already an active interrupt driven frequency output (CLKF flag is set), the active frequency output will not be stopped. Writing the CLKF flag to 0 will clear the flag and frequency output will stop. Normal and Interrupt controlled clock output can be activated concurrently.

⁽²⁾ CLKSY bit has no effect.

7.4.4. SYNCHRONIZED ENABLE/DISABLE

The enabled Synchronized FOUT Enable/Disable function (CLKSY = 1) consists of two sub-functions.

- Synchronized FOUT enable. For enabling clock output on FOUT pin the internal first negative clock edge of the selected clock source (FD field) is detected after CLKF or CLKOE are set.
- Synchronized FOUT disable. Clock output on FOUT will be disabled at the next negative clock edge of the selected clock source (FD field) after both CLKF and CLKOE are cleared and after the I²C-bus interface stop condition. When disabled, FOUT is tied to Vss.

(CLKF and CLKOE = 0 → disable condition → next negative clock edge → FOUT driven to V_{SS})

Figure 7-4 Frequency Output configuration

Hint: Glitch free frequency change on FOUT requires clearing flag CLKF and bit CLKOE to 0 before the new clock is selected in FD field.

(CLKF and CLKOE = 0 \rightarrow disable condition \rightarrow next negative clock edge \rightarrow FOUT driven to V_{SS} \rightarrow FD field selection \rightarrow CLKF and/or CLKOE = 1 \rightarrow enable condition \rightarrow next negative clock edge)

7.4.5. CLOCK OUTPUT SCHEME

Complete frequency output scheme:

- (1) See Interrupt Scheme.
 - Note that, when EIE is set and the flag EVF was cleared, the internal signal EI is generated when an External Event on EVI pin occurs, or when an Automatic Backup Switchover occurs when TSS and TSE are set to 1.
- (2) Default value on delivery for CLKOE and CLKSY (EEPROM 35h).
- (3) For the timer interrupt signal TI, the CLKSY bit has no effect.
- (4) When a frequency is enabled and the RTC module is in VBACKUP Power state, FOUT pin is LOW. When again in VDD Power state, FOUT pin outputs the frequency.

Figure 7-5 Frequency Output scheme

7.5. SETTING AND READING THE TIME

Data flow and data dependencies starting from the 1 Hz clock tick:

Figure 7-6 Setting and Reading the Time

During read/write operations, all clock and calendar registers (00h to 06h) are blocked for 950 ms second. The clock counter increment (1 Hz tick) is inhibited during I²C access to the EM3028 to allow coherent data values. A counter increment (maximum one 1 Hz tick) occurring during inhibition time is memorized and will be realized after the I²C stop condition.

Exception: If during the inhibition time the Seconds register was written by an I²C command the prescaler from 4096 Hz to 1 Hz will be reset. Resetting the prescaler will have an influence on the length of the current clock period on all subsequent peripherals (clock and calendar, FOUT, timer clock, update timer clock, UNIX clock, EVI input filter). Writing to the Seconds register has the same effect as setting RESET bit to 1 (see **RESET bit Function**).

When the read/write access has been terminated within 950 milliseconds (t < 950 ms), the time circuit is de-blocked immediately and any pending request to increment the time counters that occurred during a read access is correctly applied. Maximal one 1 Hz tick can be handled (see Figure 7-7 Access time for Read/Write Operations).

Access time for read/write operations:

Figure 7-7 Access time for Read/Write Operations

Because of this method, it is very important to make a read or write access in one go, that is, setting or reading seconds through to years should be made in one single access. Failing to comply with this method could result in the time becoming corrupted.

7.5.1. SETTING THE TIME

Advantage of register blocking during setting the time:

- Register blocking prevents faulty writing to the clock and calendar during an I²C write access (no incrementing of time registers during the write access).
- A possible 1 Hz tick occurring during the write access will be dropped.

The divider chain is reset whenever the Seconds register is written. This feature can be used to make a synchronized time setting. The other method is to use the **RESET bit Function**).

7.5.2. READING THE TIME

Advantage of register blocking and memorization of one 1 Hz tick during reading the time:

- Register blocking prevents faulty reading of the clock and calendar during an I²C read access (no incrementing of time registers during the read access).
- After reading, one memorized 1 Hz tick can be handled. Clock and calendar are updated.
- No second reading is needed. The read data are coherent.

Hint: The UNIX Time counter does not know such register blocking (see UNIX Time Counter).

7.6. EEPROM READ/WRITE

7.6.1. POR REFRESH (ALL CONFIGURATION EEPROM → RAM)

Read of all Configuration EEPROM registers at Power On Reset (POR):

At power up a refresh of the RAM mirror values by the values in the Configuration EEPROM is automatically generated (see Register Reset Values Summary). The time of this first refreshment is ~66 ms. The EEbusy bit in the register Status (0Eh) can be used to monitor the status of the refreshment.

7.6.2. AUTOMATIC REFREASH (ALL CONFIGURATION EEPROM → RAM)

Read all Configuration EEPROM registers automatically:

- To keep the integrity of the configuration data, all data of the Configuration RAM are refreshed by the data in the Configuration EEPROM each 24 hours, at date increment (1 second before midnight).
- Refresh is only active when EM3028 is not in VBACKUP mode and not disabled by EERD (EEPROM Memory Refresh Disable) bit.

7.6.3. REFRESH (ALL CONFIGURATION EEPROM → RAM)

Read all Configuration EEPROM registers:

- Before starting to read the configuration stored in the EEPROM, the auto refresh of the registers from the EEPROM has to be disabled by writing 1 into the EERD control bit.
- Then the actual configuration can be read from the Configuration EEPROM registers, writing the command 00h into the register EEcmd, and then the second command 12h into the register EEcmd will start the copy of the configuration into the RAM.
- When the transfer is finished (EEbusy = 0), the user can enable again the auto refresh of the registers by writing 0 into the EERD bit in the Control 1 register.

7.6.4. UPDATE (ALL CONFIGURATION RAM → EEPROM)

Write to all Configuration EEPROM registers:

- Before starting to change the configuration stored in the EEPROM, the auto refresh of the registers from the EEPROM has to be disabled by writing 1 into the EERD control bit.
- Then the new configuration can be written into the configuration RAM registers, when the whole new configuration is in the registers, writing the command 00h into the register EEcmd, then the second command 11h into the register EEcmd will start the copy of the configuration into the EEPROM.
- When the transfer is finished (EEbusy = 0), the user can enable again the auto refresh of the registers by writing 0 into the EERD bit in the Control 1 register.

7.6.5. READ ONE EEPROM BYTE (EEPROM → RAM-EEDATA)

Read one EEPROM byte from Configuration EEPROM or User EEPROM registers:

- Before starting to read a byte in the EEPROM, the auto refresh of the registers from the EEPROM has to be disabled by writing 1 into the EERD control bit.
- To read a single byte from EEPROM, the address to be read from is put in the EEaddr register, then the command 00h is written in the EEcmd register, then the second command 22h is written in the EEcmd register and the resulting byte can be read from the EEdata register.
- When the transfer is finished (EEbusy = 0), the user can enable again the auto refresh of the registers by writing 0 into the EERD bit in the Control 1 register.

7.6.6. WRITE TO ONE EEPROM BYTE (RAM-EEDATA → EEPROM)

Write to one EEPROM byte of the Configuration EEPROM or User EEPROM registers:

- Before starting to change data stored in the EEPROM, the auto refresh of the registers from the EEPROM has to be disabled by writing 1 into the EERD control bit.
- To write a single byte to EEPROM, the address to be written to is put in the EEaddr register and the data to be written is put in the EEdata register, then the command 00h is written in the EEcmd register, then a second command 21h is written in the EEcmd register to start the EEPROM write.
- When the transfer is finished (EEbusy = 0), the user can enable again the auto refresh of the registers by writing 0 into the EERD bit in the Control 1 register.

7.6.7. EEBUSY BIT

The set EEbusy status bit (bit 7 in the Status register 0Eh) indicates that the EEPROM is currently handling a read or write request and will ignore any further commands until the current one is finished. At power up a refresh is automatically generated. The time of this first refreshment is ~66 ms. After the refreshment is finished; EEbusy is cleared to 0 automatically. The cleared EEbusy status bit indicates that the EEPROM transfer is finished. To prevent access collision between the internal automatic EEPROM refresh cycle (EERD = 0) and external

EEPROM read/write access through interface the following procedures can be applied.

Set EERD = 1 Automatic EEPROM Refresh needs to be disabled before EEPROM access.

Check for EEbusy = 0 Access EEPROM only if not busy.

• Clear EERD = 0 It is recommended to enable Automatic EEPROM Refresh at the end of read/write

access.

Write EEPROM Wait 10 ms after each written EEPROM register before checking for EEbusy = 0 to

allow internal data transfer.

Figure 7-8 EEbusy bit

Note: In VDD Power state a minimum voltage of $V_{PROG} = 1.5 \text{ V}$ during the whole EEPROM write procedure is required; i.e. until EEbusy = 0.

7.6.8. EEPROM READ/WRITE CONDITIONS

During a read/write of the EEPROM, if the V_{DD} supply drops, the device will continue to operate and communicate until a switchover to V_{BACKUP} occurs (in DSM or LSM mode). It is not recommended to operate during this time and all I²C communication should be halted as soon as V_{DD} failure is detected.

During the time that data is being written to the EEPROM, V_{DD} should remain above the minimum programming voltage V_{PROG} = 1.5 V. If at any time V_{DD} drops below this voltage, the data written to the device get corrupted. To program the EEPROM, the backup switchover circuit must switch back to the main power supply V_{DD} . See also **Automatic BACKUP Switchover Interrupt Function**.

7.7. USE OF THE CONFIGURATION EEPROM WITH RAM MIRROR REGISTERS

The best practice method to use the Configuration EEPROM with RAM mirror registers at addresses 2Bh and 30h to 37h is to make all Configuration settings in the RAM first and then to update all Configuration EEPROMs by the Update command EEcmd = 11h, see Update (ALL CONFIGURATION RAM → EEPROM).

Edit the Configuration settings:

- 1. Enter the correct password PW (PW = EEPW) to unlock write protection (PW0 to PW3)
- 2. Disable automatic refresh (EERD = 1)
- 3. Edit Configuration settings (RAM)
 - a. For changing Password EEPW, see User Programmable Password
- 4. Enter correct password PW (PW = EEPW) to unlock write protection (PW0 to PW3)
- 5. Update EEPROM (all Configuration RAM → EEPROM) with EEcmd = 00h followed by 11h
- 6. Enable automatic refresh (EERD = 0)
- 7. Enter an incorrect password PW (PW ≠ EEPW) to (PW0 to PW3) to lock the device

7.8. INTERRUPT OUTPUT

The interrupt pin nINT can be triggered by six different functions:

- Periodic Countdown Timer Interrupt F
- Periodic Time Update Interrupt F
- Alarm Interrupt F
- External Event F
- Automatic BACKUP Switchover Interrupt F
- POWER ON RESET Interrupt F

7.8.1. SERVICING INTERRUPTS

The nINT pin can indicate six types of interrupts. It outputs the logic OR operation result of these interrupt outputs. When an interrupt is detected (when nINT pin produces a negative pulse or is at low level), the TF, UF, AF, EVF, BSF and PORF flags can be read to determine which interrupt event has occurred.

To keep nINT pin from changing to low level, clear the TIE, UIE, AIE, EIE and BSIE (EEPROM 37h) and PORIE (EEPROM 35h) bits. To check whether an event has occurred without outputting any interrupts via the nINT pin, software can read the TF, UF, AF, EVF, BSF and PORF interrupt flags (polling).

Caution: The EVF flag is also set by an event of the Backup Switchover function when bits TSS and TSE are set to 1.

7.8.2. INTERRUPT SCHEME

Interrupt Scheme (Part 1)

- (1) Only when all enabled alarm settings are matching.It is only on increment to a matched case that the Alarm Flag AF is set.
- (2) When bits TIE, UIE, AIE, EIE and BSIE (EEPROM 37h) and PORIE (EEPROM 35h) are disabled, pin nINT remains high impedance.
- (3) See Clock Output Scheme.

Figure 7-9 Interrupt Scheme (Part 1)

Interrupt Scheme (Part 2) to interface: read EVF EIE Part 1 time stamp EHL, ET scheme **EVENT FLAG** EVF SET EXT. EVENT FUNCTION CLEAR (3) EI TSS (4) TSE from interface: clear EVF to interface: read BSF BSIE time stamp BSM, FEDE (2)scheme BACKUP FLAG nINT OR AUTOMATIC BACKUP **BSF** SET ≥1 SWITCHOVER FUNCTION **CLEAR** from interface: to interface: clear BSF read PORF PORIE POR FLAG **PORF** POWER ON RESET SET **POR CLEAR** from interface: clear PORF

- (2) When bits TIE, UIE, AIE, EIE and BSIE (EEPROM 37h) and PORIE (EEPROM 35h) are disabled, pin nINT remains high impedance.
- (3) See Clock Output Scheme. Note that, when EIE is set and the flag EVF was cleared, the internal signal EI is generated when an External Event on EVI pin occurs, or when an Automatic Backup Switchover occurs when TSS and TSE
- (4) Caution: The EVF flag is also set by an event of the Backup Switchover function when bits TSS and TSE are set to 1.

Figure 7-10 Interrupt Scheme (Part 2)

7.9. PERIODIC COUNTDOWN TIMER INTERRUPT FUNCTION

The Periodic Countdown Timer Interrupt function generates an interrupt event once or periodically at any period set from 244.14 µs to 4095 minutes.

If TRPT is set to 0 (default), Single Mode is selected. In Single Mode the counter will stop after reaching 0 and bit TE will be reset.

TRPT bit has to be set to 1 if periodic countdown is needed (Repeat Mode). In Repeat Mode the timer will be reloaded with the Timer Value from the Timer Value 0 and Timer Value 1 registers. This will repeat until TE is cleared or TRPT will be set to 0. In later case the countdown will stop when the timer reaches 0 for the next time and TE will be cleared. Loading the Timer Value with 0 stops the timer, interrupt is cleared and the flag TF is reset.

When starting the countdown timer for the first time, only the first period does not have a fixed duration. The amount of inaccuracy for the first timer period depends on the selected source clock (see **First Period Duration**).

When an interrupt event is generated, the nINT pin goes to the low level and the TF flag is set to 1 to indicate that an event has occurred. The output on the nINT pin is only effective if the TIE bit in the Control 2 register is set to 1. The low-level output signal on the nINT pin is automatically cleared after the Auto reset time t_{RTN1} . $t_{RTN1} = 122 \,\mu s$ (TD = 00) or $t_{RTN1} = 7.813 \,ms$ (TD = 01, 10, 11).

When bit TIE is set to 1, the internal countdown timer interrupt pulse (TI) can be used to enable the clock output on FOUT pin automatically, when bits CTIE, CLKIE and CLKOE are set to 1 and a frequency is selected in the FD field. The interrupt pulses (TI) can even be used as FOUT frequency, when selecting 110 in the FD field (see Clock Output Scheme).

7.9.1. PERIODIC COUNTDOWN TIMER DIAGRAM

Diagram of the Periodic Countdown Timer Interrupt function: In Repeat Mode (TRPT = 1). Countdown Timer Signal on FOUT (CLKOE = 1 and FD = 110).

- The Periodic Countdown Timer starts from the preset Timer Value when writing a 1 to the TE bit. The countdown is based on the Timer Clock Frequency. For Repeat Mode, TRPT has to be set to 1.
- ^② When the count value reaches 000h, an interrupt event occurs. After the interrupt, when TRPT = 1, the counter is automatically reloaded with the preset Timer Value, and starts again the countdown.
- ^③ When a Periodic Countdown Timer Interrupt occurs, the TF flag is set to 1.
- The TF flag retains 1 until it is cleared to 0 by software.
- (5) If the TIE bit is 1 and a Periodic Countdown Timer Interrupt occurs, the nINT and FOUT output pins go low.
- The nINT and FOUT output pins remains LOW during the Auto reset time t_{RTN1}, and then they are automatically cleared to 1. The TD field determines the Timer Clock Frequency and the Auto reset time t_{RTN1}. t_{RTN1} = 122 μs (TD = 00) or t_{RTN1} = 7.813 ms (TD = 01, 10, 11).
- When a 0 is written to the TE bit, the Periodic Countdown Timer function is stopped and the nINT and FOUT pins are cleared after the Auto reset time t_{RTN1}.
- [®] If the nINT and FOUT pins are LOW, their status do not change when the TF flag is cleared to 0.
- (9) If the nINT pin is LOW, its status changes as soon as the TIE bit value is cleared to 0.

Figure 7-11 Periodic Countdown Timer Interrupt

7.9.2. USE OF THE PERIODIC COUNTDOWN TIMER INTERRUPT

The following registers, fields and bits are related to the Periodic Countdown Timer Interrupt and Automatic Clock output function:

- Timer Value 0 Register (0Ah) (see Periodic Countdown Timer Control Registers)
- Timer Value 1 Register (0Bh) (see Periodic Countdown Timer Control Registers)
- Timer Status 0 Register (0Ch) (see Periodic Countdown Timer Control Registers)
- Timer Status 1 shadow Register (0Dh) (see Periodic Countdown Timer Control Registers)
- TF flag (see Configuration Registers, 0Eh Status)
- TRPT bit, TE bit and TD field (see Configuration Registers, 0Fh Control 1)
- TIE bit (see Configuration Registers, 10h Control 2)
- CTIE bit (see Configuration Registers, 12h Clock Interrupt Mask)

For selecting Countdown Timer Signal for FOUT pin (CLKOE = 1 and FD = 110):

• CLKOE bit and FD field (see **EEPROM FOUT Register**)

Prior to entering any timer settings for the Periodic Countdown Timer Interrupt, it is recommended to write a 0 to the TIE and TE bits to prevent inadvertent interrupts on nINT pin. When 1 is written to the RESET bit, the Periodic Countdown Timer Interrupt function is retarded. When the Periodic Countdown Timer Interrupt function is not used, one Timer Value register (0Ah) can be used as RAM byte. The Timer Clock Frequency selection field TD is used to set the countdown period (source clock) for the Periodic Countdown Timer Interrupt function (four settings are possible).

Procedure to use the Periodic Countdown Timer Interrupt function and Automatic Clock output function:

- 1. Initialize bits TE, TIE and TF to 0. In that order, to prevent inadvertent interrupts on nINT pin.
- 2. Set TRPT bit to 1 if periodic countdown is needed (Repeat Mode).
- 3. Choose the Timer Clock Frequency and write the corresponding value in the TD field.
- 4. Choose the Countdown Period based on the Timer Clock Frequency, and write the corresponding Timer Value to the registers Timer Value 0 (0Ah) and Timer Value 1 (0Bh). See following table.
- 5. Set the TIE bit to 1 if you want to get a hardware interrupt on nINT pin.
- 6. Set CTIE bit to 1 to enable clock output when a timer interrupt occurs. See also Clock Output Scheme).
- 7. Set the TIE and CLKOE bits to 1 and the FD field to 110 if you want to get the timer signal on FOUT.
- 8. Set the TE bit from 0 to 1 to start the Periodic Countdown Timer. The countdown starts at the rising edge of the SCL signal after Bit 0 of the Address 0Fh is transferred. See subsequent Figure that shows the start timing.

Countdown Period in seconds:

$$Countdown Period = \frac{Timer Value}{Timer Clock Frequency}$$

Timer Value	Countdown Period							
(0Ah and 0Bh)	TD = 00 (4096 Hz)	TD = 01 (64 Hz)	TD = 10 (1 Hz)	TD = 11 (1/60 Hz))				
0	-	-	-	-				
1	244.14 µs	15.625 ms	1 s	1 min				
2	488.28 μs	31.25 ms	2 s	2 min				
:	:	:	:	:				
41	10.010 ms	640.63 ms	41 s	41 min				
205	50.049 ms	3.203 s	205 s	205 min				
410	100.10 ms	6.406 s	410 s	410 min				
2048	500.00 ms	32.000 s	2048 s	2048 min				
:	:	:	:	:				
4095 (FFFh)	0.9998 s	63.984 s	4095 s	4095 min				

Figure 7-12 Periodic Countdown Timer Interrupt

Figure 7-13 Periodic Countdown Timer Interrupt, countdown starting synchronization

7.9.3. FIRST PERIOD DURATION

When the TF flag is set, it indicates that an interrupt signal on nINT is generated if this mode is enabled. See Section **Interrupt Output** for details on how the interrupt can be controlled.

When starting the timer for the first time, the first period has an uncertainty. The uncertainty is a result of the enable instruction being generated from the interface clock which is asynchronous from the Timer Clock Frequency. Subsequent timer periods do not have such deviation. The amount of deviation for the first timer period depends on the chosen Timer Clock Frequency, see following Table.

First period duration for Timer Value $n^{(1)}$:

-	Timer Clock	First perio	Subsequent	
TD	Frequency	Minimum Period	Maximum Period	periods duration
00	4096 Hz	n * 244 µs	(n + 1) * 244 μs	n * 244 μs
01	64 Hz	n * 15.625 ms	(n +1) * 15.625 ms	n * 15.625 ms
10	1 Hz	n * 1 s	n * 1 s + 15.625 ms	n * 1 s
11	1/60 Hz	n * 60 s	n * 60 s + 15.625 ms	n * 60 s
(1)				

⁽¹⁾ Timer Values n from 1 to 4095 are valid. Loading the counter with 0 stops the timer.

At the end of every countdown, the timer sets the Periodic Countdown Timer Flag (bit TF in Status Register). Bit TF can only be cleared by command. When enabled, a pulse is generated at the interrupt pin nINT.

When reading the Timer Value (Timer Value 0 and Timer Value 1), the preset value is returned and not the actual value. The actual value of the Periodic Countdown Timer can be read in the registers Timer Status 0 and Timer Status 1.

7.10. PERIODIC TIME UPDATE INTERRUPT FUNCTION

The Periodic Time Update Interrupt function generates an interrupt event periodically at the One-Second or the One-Minute update time, according to the selected timer source with bit USEL.

When an interrupt event is generated, the nINT pin goes to the low level and the UF flag is set to 1 to indicate that an event has occurred. The output on nINT pin is only effective if UIE bit in Control 2 register is set to 1. The low-level output signal on the nINT pin is automatically cleared after the Auto reset time t_{RTN2} . $t_{RTN2} = 500$ ms (Second update) or $t_{RTN2} = 7.813$ ms (Minute update).

When bit UIE is set to 1, the internal update interrupt pulse (UI) can be used to enable the clock output on FOUT pin automatically, when bits CUIE, CLKIE and CLKOE are set to 1 and a frequency is selected in the FD field (see Clock Output Scheme).

7.10.1. PERIODIC TIME UPDATE DIAGRAM

Diagram of the Periodic Time Update Interrupt function:

- ① A Periodic Time Update Interrupt event occurs when the internal clock value matches either the second or the minute update time. The USEL bit determines whether it is the Second or the Minute period with the corresponding Auto reset time tring. tring = 500 ms (Second update) or tring = 7.813 ms (Minute update).
- When a Periodic Time Update Interrupt occurs, the flag UF is set to 1.
- ³ The UF flag retains 1 until it is cleared to 0 by software.
- (4) If the UIE bit is 1 and a Periodic Time Update Interrupt occurs, the nINT pin output goes low.
- (5) The nINT pin output remains low during the Auto reset time tRTN2, and then it is automatically cleared to 1.
- 6 If the nINT pin is low, its status does not change when the UF flag is cleared to 0.
- (7) If the nINT pin is low, its status changes as soon as the UIE bit value is cleared to 0.

Figure 7-14 Periodic Time Update Interrupt

7.10.2. USE OF THE PERIODIC TIME UPDATE INTERRUPT

The following bits are related to the Periodic Time Update Interrupt and Automatic Clock output function:

- UF flag (see Configuration Registers, 0Eh Status)
- USEL bit (see Configuration Registers, 0Fh Control 1)
- UIE bit (see Configuration Registers, 10h Control 2)
- CUIE bit (see Configuration Registers, 12h Clock Interrupt Mask)

Prior to entering any other settings, it is recommended to write a 0 to the UIE bit to prevent inadvertent interrupts on nINT pin. The Periodic Time Update Interrupt function cannot be fully stopped, but by writing a 0 in the UIE bit, it prevents the occurrence of a hardware interrupt on the nINT pin.

When 1 is written to the RESET bit (see **Configuration Registers**, 10h – Control 2) the divider chain is reset and the Periodic Time Update Interrupt will be retarded. The reset function only interrupts the Periodic Time Update Interrupt function but does not turn it off.

Procedure to use the Periodic Time Update Interrupt and Automatic Clock output function:

- 1. Initialize bits UIE and UF to 0.
- 2. Choose the timer source clock and write the corresponding value in the USEL bit.
- 3. Set the UIE bit to 1 if you want to get a hardware interrupt on nINT pin.
- Set CUIE bit to 1 to enable clock output when a time update interrupt occurs. See also Clock Output Scheme.
- 5. The first interrupt will occur after the next event, either second or minute change.

7.11. ALARM INTERRUPT FUNCTION

The Alarm Interrupt function generates an interrupt for alarm settings such as weekday/date, hour and minute settings.

When an interrupt event is generated, the nINT pin goes to the low level and the AF flag is set to 1 to indicate that an event has occurred. The output on the nINT pin is only effective if the AIE bit in the Control 2 register is set to 1.

When bit AIE is set to 1, the internal alarm interrupt signal (AI) can be used to enable the clock output on FOUT pin automatically, when bits CAIE, CLKIE and CLKOE are set to 1 and a frequency is selected in the FD field (see Clock Output Scheme).

7.11.1. ALARM DIAGRAM

Diagram of the Alarm Interrupt function:

- ① A weekday/date, hour or minute alarm interrupt event occurs when all selected Alarm registers (AE_x bits) match to the respective counters. The WADA bit determines whether it is the weekday or date.
- ² When an Alarm Interrupt event occurs, the AF flag is set to 1.
- ^③ The AF flag retains 1 until it is cleared to 0 by software.
- (4) If the AIE bit is 1 and an Alarm Interrupt occurs, the nINT pin output goes low.
- (§) If the AIE value is changed from 1 to 0 while the nINT pin output is low, the nINT pin immediately changes its status. While the AF flag is 1, the nINT status can be controlled by the AIE bit.
- (6) If the nINT pin is low, its status changes as soon as the AF flag is cleared from 1 to 0.
- The AIE bit value is 0 when an Alarm Interrupt occurs, the nINT pin status does not go low.

Figure 7-15 Alarm Interrupt

7.11.2. USE OF THE ALARM INTERRUPT

The following registers and bits are related to the Alarm Interrupt and Automatic Clock output function:

- Minutes Register (01h) (see Clock Registers)
- Hours Register (02h) (see Clock Registers)
- Weekday Register (03h) (see Calendar Registers)
- Date Register (04h) (see Calendar Registers)
- Minutes Alarm Register and AE_M bit (07h) (see Alarm Registers)
- Hours Alarm Register and AE_H bit (08h) (see Alarm Registers)
- Weekday/Date Alarm Register and AE_WD bit (09h) (see Alarm Registers)
- AF flag (see Configuration Registers, 0Eh Status)
- WADA bit (see Configuration Registers, 0Fh Control 1)
- AIE bit (see Configuration Registers, 10h Control 2)
- CAIE bit (see Configuration Registers, 12h Clock Interrupt Mask)

Prior to entering any timer settings for the Alarm Interrupt, it is recommended to write a 0 to the AIE bit to prevent inadvertent interrupts on nINT pin. When 1 is written to the RESET bit, an Alarm Interrupt function event can be retarded. When the Alarm Interrupt function is not used, one Byte (07h) of the Alarm registers can be used as RAM byte. In such case, be sure to write a 0 to the AIE bit (if the AIE bit value is 1 and the Alarm register is used as RAM register, nINT may change to low level unintentionally).

Procedure to use the Alarm Interrupt and Automatic Clock output function:

- 1. Initialize bits AIE and AF to 0.
- 2. Choose weekday alarm or date alarm (weekday/date) by setting the WADA bit. WADA = 0 for weekday alarm or WADA = 1 for date alarm.
- 3. Write the desired alarm settings in registers 07h to 09h. The three alarm enable bits, AE_M, AE_H and AE_WD, are used to select the corresponding register that has to be taken into account for match or not. See the following table.
- 6. Set CAIE bit to 1 to enable clock output when an alarm occurs. See also Clock Output Scheme.
- 4. Set the AIE bit to 1 if you want to get a hardware interrupt on nINT pin.

Alarm Interrupt:

Alarm enable bits		bits	Alarm event					
AE_WD	AE_H	AE_M						
0	0	0	When minutes, hours and weekday/date match (once per weekday/date)					
0	0	1	When hours and weekday/date match (once per weekday/date)					
0	1	0	When minutes and weekday/date match (once per hour per weekday/date)					
0	1	1	When weekday/date match (once per weekday/date)					
1	0	0	When hours and minutes match (once per day)					
1	0	1	When hours match (once per day)					
1	1	0	When minutes match (once per hour)					
1	1	1	All disabled – Default value					
ΛΓ v bita	/whore w	io W/D L	Lor M)					

AE_x bits (where x is WD, H or M)

 $AE_x = 0$: Alarm is enabled

AE_x = 1: Alarm is disabled - Default value

7.12. EXTERNAL EVENT FUNCTION

The External Event Interrupt and the Time Stamp function are enabled by the control bits EIE, TSS and TSE. Depending of the EHL bit a high level (positive edge) or low level (negative edge) signal can be regarded as an event and furthermore a digital glitch filtering is applied to the EVI signal when selecting a sampling period in the ET field.

If enabled (EIE = 1, TSS = 0, TSE = 1 and EVF flag was cleared to 0 before) and an External Event on EVI pin is detected, the clock and calendar registers are captured and copied into the Time Stamp registers, the nINT is issued and the EVF flag is set to 1 to indicate that an external event has occurred.

When bit EIE is set to 1, the internal event interrupt signal (EI) can be used to enable the clock output on FOUT pin automatically, when bits CEIE, CLKIE and CLKOE are set to 1 and a frequency is selected in the FD field (see Clock Output Scheme).

Caution: The EVF flag is also set by an event of the Backup Switchover function when bits TSS and TSE are set to 1.

7.12.1. EXTERNAL EVENT DIAGRAM

Diagram of the External Event function. Example with positive edge/level detection (EHL = 1):

- ① Initialize clock and calendar and set TSE bit to 1 if Time Stamp is needed and EIE bit to 1 if interrupt on nINT pin is required. The EVF flag needs to be cleared to reset the nINT pin and to prepare the system for an event. In this example, EHL is set to 1 for positive edge detection. The Time Stamp Source Selection bit TSS = 0 for External Event function.
- ^② An External Event on EVI pin is detected. Pay attention to the debounce time when using the filtering (ET field). The value (A+1) is captured/copied into the TS registers and the value in the Count TS register is incremented by one. The counter Count TS is always working, independent of the settings of the overwrite bit TSOW.
- ^③ When an External Event Interrupt occurs, the EVF flag is set to 1.
- (4) If the EIE bit is 1 and an External Event Interrupt occurs, the nINT pin output goes low.
- ^⑤ The EVF flag retains 1 until it is cleared to 0 by software.
- ⁽⁶⁾ No interrupt occurs on nINT pin because the EVF flag was not set back to 0. But, new value (A+2) is captured in the TS registers if the Time Stamp overwrite bit TSOW is set to 1.
- (7) If the nINT pin is low, its status changes as soon as the EVF flag is cleared to 0, even if EVI input is high level.
- ® If TSE is set to 0, no time stamp is captured.
- ⁽⁹⁾ If the EVI input is 1 (steady state) and the TSE bit is set from 0 to 1, no event is detected.
- 10 While the EVF flag is 1, the nINT status can be controlled by the EIE bit.
- When TSR bit is set to 1, all seven time stamp registers (Count TS to Year TS) are cleared to 00h. The TSR bit is automatically cleared to 0 after performing the reset.

Figure 7-16 External Event

7.12.2. USE OF THE EXTERNAL EVENT FUNCTION

The following registers and bits are related to the External Event Interrupt, Time Stamp and Automatic Clock output function:

- Seconds Register (00h) (see Clock Registers)
- Minutes Register (01h) (see Clock Registers)
- Hours Register (02h) (see Clock Registers)
- Date Register (04h) (see Calendar Registers)
- Month Register (05h) (see Calendar Registers
- Year Register (06h) (see Calendar Registers)
- Count TS Register (14h) (see Time Stamp Registers)
- Seconds TS (15h) (see Time Stamp Registers)
- Minutes TS (16h) (see Time Stamp Registers)
- Hours TS (17h) (see Time Stamp Registers)
- Date TS (18h) (see Time Stamp Registers)
- Month TS (19h) (see Time Stamp Registers)
- Year TS (1A) (see Time Stamp Registers)
- EVF flag (see Configuration Registers, 0Eh Status)
- TSE and EIE bits (see Configuration Registers, 10h Control 2)
- CEIE bit (see Configuration Registers, 12h Clock Interrupt Mask)
- EHL bit, ET field, TSR bit, TSOW bit and TSS bit (see Event Control Register)

Prior to entering any timer settings for the event interrupt, it is recommended to write a 0 to the EIE bit to prevent inadvertent interrupts on nINT pin.

Procedure to use the External Event Interrupt, Time Stamp and Automatic Clock output function:

- 1. Initialize bits TSE, EIE and flag EVF to 0.
- 2. Set TSR bit to 1, to reset all Time Stamp registers to 00h. After reset the TSR bit is automatically cleared.
- 3. Set EHL bit to 1 or 0 to choose high or low level detection on pin EVI.
- 4. Set ET field to apply filtering to the EVI pin. See following two diagrams.
- 5. Set TSS bit to 0 to select External Event on EVI pin as Time Stamp source.
- 6. Set TSOW bit to 1 if the last occurred event has to be recorded and TS registers are overwritten. Hint: The counter Count TS is always working, independent of the settings of the overwrite bit TSOW.
- 7. Set CEIE bit to 1 to enable clock output when external event occurs. See also Clock Output Scheme.
- 8. Set TSE bit to 1 if you want to enable the Time Stamp function.
- 9. Set EIE bit to 1 if you want to get a hardware interrupt on nINT pin.

Figure 7-17 External Event function, No filtering example, EIE = 1

Example with digital debounce filtering (ET = 01, 10 or 11; sampling period t_{SP} = 3.9 ms, 15.6 ms or 125 ms), with positive edge/level detection (EHL = 1) and enabled interrupt (EIE = 1):

- ① Up to this sampling pulse a positive edge was detected but no steady state.
- ② If a positive edge was detected and a steady state (high level) was detected during a complete sampling period (between ③ and ②) the nINT pin output goes low. The delay time t_{DELAY} varies between t_{SP} and (2 x t_{SP}) depending on the bouncing signal on the EVI pin.

Figure 7-18 External Event function, with Filtering example, EIE = 1

7.13. AUTOMATIC BACKUP SWITCHOVER INTERRUPT FUNCTION

The Automatic Backup Switchover Interrupt function generates an interrupt event when the BSM field (EEPROM 37h) is set to 01 (DSM) or 11 (LSM) and a switchover from VDD Power state to VBACKUP Power state occurs.

When an interrupt event is generated, the nINT pin goes to the low level and the BSF flag is set to 1 to indicate that an event has occurred. The output on the nINT pin is only effective if the BSIE bit (EEPROM 37h) is set to 1.

When bit EIE is set to 1 and when the bits TSS and TSE are set to 1, the internal event interrupt signal (EI) created by the Automatic Backup Switchover function can be used to enable the clock output on FOUT pin automatically, when bits CEIE, CLKIE and CLKOE are set to 1 and a frequency is selected in the FD field. When again in VDD Power state, FOUT pin outputs the frequency (see Clock Output Scheme).

Hint: A debounce logic provides a 122 μs – 183 μs debounce time t_{DEB} , which will filter V_{DD} oscillation when the backup switchover will switch back from V_{BACKUP} to V_{DD} (see **AUTOMATIC BACKUP Switchover Function**).

Hint: The FEDE bit (EEPROM 37h) should always be set to 1, so that Fast Edge Detection (≥ 7 V/ms) is always enabled (see **EEPROM BACKUP Register**). – Default value on delivery

7.13.1. AUTOMATIC BACKUP SWITCHOVER DIAGRAM

Diagram of the Automatic Backup Switchover Interrupt function:

- ① Initialize clock and calendar and set TSE bit to 1 if Time Stamp is needed and BSIE bit (EEPROM 37h) to 1 if interrupt on nINT pin is required. The BSF flag needs to be cleared to reset the nINT pin and to prepare the system for an event. To enable switchover function the BSM field (EEPROM 37h) is set to 01 (DSM) or 11 (LSM). The Time Stamp Source Selection bit TSS has to be set to 1 to select the Backup Switchover function.
- ^② A backup switchover from VDD Power state to VBACKUP Power state occurs. The value (A+1) is captured/copied into the TS registers and the value in the Count TS register is incremented by one. The counter Count TS is always working, independent of the settings of the overwrite bit TSOW.
- ^③ When an Automatic Backup Switchover Interrupt event occurs, the BSF flag is set to 1.
- (4) If the BSIE bit is 1 and a Backup Switchover Interrupt occurs, the nINT pin output goes low.
- ^⑤ The BSF flag retains 1 until it is cleared to 0 by software.
- ⁽⁶⁾ No interrupt occurs on nINT pin because the BSF flag was not set back to 0. But, new value (A+2) is captured in the TS registers if the Time Stamp overwrite bit TSOW is set to 1.
- (7) If the nINT pin is low, its status changes as soon as the BSF flag is cleared to 0.
- ® If TSE is set to 0, no time stamp is captured.
- (9) If BSF is 1 and the TSE bit is set from 0 to 1, no event is detected.
- $^{\textcircled{10}}$ While the BSF flag is 1, the nINT status can be controlled by the BSIE bit.
- When TSR bit is set to 1, all seven time stamp registers (Count TS to Year TS) are cleared to 00h. The TS bit is automatically cleared to 0 after performing the reset.

Figure 7-19 Automatic Backup Switchover

7.13.2. USE OF THE AUTOMATIC BACKUP SWITCHOVER INTERRUPT

The following registers and bits are related to the Automatic Backup Switchover Interrupt, Time Stamp and Automatic Clock output function:

- Seconds Register (00h) (see Clock Registers)
- Minutes Register (01h) (see Clock Registers)
- Hours Register (02h) (see Clock Registers)
- Date Register (04h) (see Calendar Registers)
- Month Register (05h) (see Calendar Registers)Error! Reference source not found.
- Year Register (06h) (see Calendar Registers)
- Count TS (14h) (see Time Stamp Registers)
- Seconds TS (15h) (see Time Stamp Registers)
- Minutes TS (16h) (see **Time Stamp Registers**)
- Hours TS (17h) (see **Time Stamp Registers**)
- Date TS (18h) (see Time Stamp Registers)
- Month TS (19h) (see Time Stamp Registers)
- Year TS (1A) (see Time Stamp Registers)
- BSF flag (see Configuration Registers, 0Eh Status)
- CEIE bit (see Configuration Registers, 12h Clock Interrupt Mask)
- TSR bit, TSOW bit and TSS bit (see Event Control Register)
- BSIE bit, FEDE bit and BSM field (see **EEPROM BACKUP Register**)

Prior to entering any other settings, it is recommended to write a 0 to the BSIE bit to prevent inadvertent interrupts on nINT pin.

Procedure to use the Automatic Backup Switchover Interrupt, Time Stamp and Automatic Clock output function:

- 1. Initialize bits TSE, BSIE and BSF to 0.
- 2. Set TSR bit to 1, to reset all Time Stamp registers to 00h. After reset, the TSR bit is automatically cleared.
- 3. Set TSS bit to 1 to select Backup Switchover as Time Stamp source.
- 4. Set TSOW bit to 1 if the last occurred event has to be recorded and TS registers are overwritten. Hint: The counter Count TS is always working, independent of the settings of the overwrite bit TSOW.
- 5. Set TSE bit to 1 if you want to enable the Time Stamp function.
- 6. Set CEIE bit to 1 to enable clock output when a backup switchover occurs.

 Caution: This function is only working with the Automatic Backup Switchover function when the bits TSS and TSE are set to 1. See also Clock Output Scheme.
- 7. The FEDE bit (EEPROM 37h) should always be set to 1, so that Fast Edge Detection (≥ 7 V/ms) is always enabled.
- 8. Set the BSIE bit to 1 (EEPROM 37h) if you want to get a hardware interrupt on nINT pin.
- 9. Choose the switchover mode (DSM or LSM) and write the corresponding value in the BSM field.

See also **EEPROM Read/Write Conditions**.

7.14. POWER ON RESET INTERRUPT FUNCTION

The Power On Reset Interrupt function is enabled by the PORIE bit (EEPROM 35h).

The PORIE bit has to be set beforehand in the EEPROM not in the RAM (see EEPROM READ/WRITE)

When voltage drop below V_{POR} is detected ($V_{DD} < V_{POR}$) the PORF flag is set to 1 to indicate that a Power On Reset has occurred and when the PORIE bit is 1 the nINT pin goes to low level.

A PORF value of 1 indicates also that the time information is corrupted. The value 1 is retained until a 0 is written by the user.

7.14.1. POWER ON RESET DIAGRAM

Diagram of the Power On Reset Interrupt function:

- → Write operation (I²C access only in VDD Power state)
- $^{\textcircled{1}}$ Flag PORF is set when V_{DD} was below V_{POR} . Software can read it after t_{START} when the RTC is operating.
- ② If the PORIE bit (EEPROM 35h) was set to 1 beforehand (in EEPROM), the PORIE bit in the RAM is set to 1 after the start-up time $t_{START} = 0.5$ s and the first refreshment time $t_{REFR} = \sim 66$ ms.
- ^③ If the PORIE bit is 1 and a Power On Reset event occurs, the nINT pin output goes low after a delay time of $t_{DELAY} = \sim 1$ ms.
- ⁽⁴⁾ The PORF flag retains 1 until it is cleared to 0 by software.
- ^⑤ While the PORF flag is 1, the nINT status can be controlled by the PORIE bit.
- 6 If the nINT pin is low, its status changes as soon as the PORF flag is cleared to 0.
- The Porision of the Porision
- If the PORIE bit is 1 when a Power On Reset event occurs, the nINT pin output goes low after a delay time of t_{DELAY} = ~1 ms. Or else, if the PORIE bit is 0 when a Power On Reset event occurs, the nINT pin output does not go low.

Figure 7-20 Power On Reset Interrupt

7.14.2. USE OF THE POWER ON RESET INTERRUPT

The following registers and bits are related to the Power On Reset Interrupt function (including EEPROM handling):

- PORF flag and EEbusy bit (see Configuration Registers, 0Eh Status)
- EERD bit (see Configuration Registers, 0Fh Control 1)
- EEaddr register (see EEPROM Memory Control Registers, 25h –EEPROM Address)
- EEdata register (see **EEPROM Memory Control Registers**, 26h –EEPROM Data)
- EEcmd register (see EEPROM Memory Control Registers, 27h –EEPROM Commands
- PORIE bit (see **EEPROM FOUT Register**, 35h EEPROM FOUT)

The PORIE bit has to be set beforehand in the EEPROM not in the RAM (see EEPROM READ/WRITE).

Procedure to use the Power On Reset Interrupt function:

- 1. In the EEPROM, set the PORIE bit to 1 if you want to get a hardware interrupt on nINT pin at the next Power On Reset event. Procedure according to **EEPROM READ/WRITE**.
- 2. The first interrupt will occur after the next POR event.

7.15. TIME STAMP FUNCTION

The Time Stamp function is enabled by the control bit TSE. Sources are the External Event function (TSS = 0) or the Automatic Backup Switchover function (TSS = 1).

If a source is enabled and an event is detected, the Time Stamp (TS) registers are recorded. When the TSOW bit is set to 0 and the EVF flag was cleared to 0 before, only one (the first) event is recorded. When the TSOW bit is set to 1, the last event is recorded (EVF flag does not need to be cleared). The counter Count TS is always working, independent of the settings of the overwrite bit TSOW.

- When the TSR bit value is 1, the data of the time stamp in TS registers and Count TS are reset.
- Before writing settings for TS, it is recommended to write a 0 in the TSE bit and a 1 to EVR bit.
- When 1 is written to the RESET bit, the TS event can be retarded.

Procedures to use the Time Stamp function with the External Event Interrupt function or with the Automatic Backup Switchover function:

- 1. Write 0 in TSS and TSE bits. Select TSOW (0 or 1), clear EVF and BSF.
- 2. Write 1 in TSR bit then it is automatically cleared after performing the reset.
- 3. Write the desired external event or backup switchover settings (enabling function and interrupt on nINT pin):
 - a. See External Event Function
 - b. See Automatic BACKUP Switchover Interrupt Function
 - 4. Set the TSE bit to 1 to enable the Time Stamp function.

Hint: The nINT signal is issued when EIE (RAM) or BSIE (EEPROM 37h) bit is set to 1. The EVF or BSF flag is set to 1 to indicate that a corresponding event has occurred.

Caution: Because the EVF flag is internally used for the identification of a First Event detection it is set by an event from the External Event function (TSS = 0, TSE = 1) or by an event of the Backup Switchover function (TSS = 1, TSE = 1). See also following scheme.

Complete Time Stamp scheme: RESET auto 1 Hz tick Seconds EHL. ET Minutes Hours interface: Interrupt **EXT. EVENT FUNCTION** read/write scheme Date Month Year **TSS TSE** Time Stamp capture/copy auto BSM, FEDE Count TS AUTOMATIC BACKUP Interrupt Seconds TS SWITCHOVER FUNCTION scheme **TSR** (3)Minutes TS interface: (5) Hours TS read only Interrupt auto Date TS clear scheme Month TS Year TS TSOW EVF (1)AND OR enable overwrite first event & ≥1

- (1) When TSOW bit is set to 1 the TS registers (Seconds TS to Year TS) are overwritten. The last occurred event is recorded. When TSOW bit is set to 0, the TS registers are overwritten once only. To initialize or reinitialize the first event function, the EVF has to be cleared (the TS registers can be cleared by writing 1 to the TSR bit). The counter Count TS is always working, independent of the settings of the overwrite bit TSOW.
- (2) If set to 0 beforehand, the EVF flag indicates the occurrence of an External Event. The value 1 is retained until a 0 is written by the user.
 Caution: The EVF flag is also set by an event of the Backup Switchover function when bits TSS and TSE are set to 1.
- (3) When TSR bit is set to 1, all seven time stamp registers (Count TS to Year TS) are cleared to 00h. The TSR bit is automatically cleared to 0 after performing the reset.
- (4) When 1 is written to the RESET bit, the Time Stamp event does not occur. The RESET bit is automatically cleared to 0 after performing the reset.
- (5) During I²C read access to the TS registers the time stamp capture function is blocked.

Figure 7-21 Time Stamp Scheme

last event

7.16. FREQUENCY OFFSET CORRECTION

An aging adjustment or accuracy tuning can be done with the EEOffset value. The correction is purely digitally and has only the effect of shifting the time vs. temperature curve vertically up or down. It has no effect on the time vs. temperature characteristics of the final frequency. The EEOffset value contains a two's complement number with a range of +255 to -256 adjustment steps. The minimal correction step (one LSB) is $\pm 1/(32768*32) = \pm 0.9537$ ppm. The compensation period is 32 seconds. The maximum correction range is from +243.2 ppm to -244.1 ppm.

Note that the signed offset value EEOffset corresponds to the correction value of the measured frequency (32.768 kHz). The user has access to this field (see **EEPROM OFFSET Register**).

7.16.1. EEOFFSET VALUE DETERMINATION

The EEOffset value is determined by the following process:

- Select the 32.768 kHz frequency on the FOUT pin. (If another frequency than 32.768 kHz is selected, the EEOffset value has to be set to 0 so that the uncorrected frequency can be measured, and the following calculations have to be adapted.)
- 2. Measure the frequency Fmeas at FOUT pin in Hz.
- 3. Compute the offset value required in ppm: POffset = ((Fmeas 32768) / 32768 * 1'000'000)
- 4. Compute the offset value in steps: Offset = POffset / (1 / (32768*32) in ppm) = POffset / (0.9537 ppm)
- 5. If Offset > 256, the frequency is too high to be corrected.
- 6. Else if 1 ≤ Offset ≤ 256 (correction is -1 ≥ OffsetCorr. ≥ -256), → set EEOffset = 512 Offset
- 7. Else if -255 ≤ Offset ≤ 0 (correction is +255 ≤ OffsetCorr. ≤ 0), → set EEOffset = Offset
- 8. Else the frequency is too low to be corrected.

Examples:

- If 32768.48 Hz is measured when the 32.768 kHz clock is selected, the offset is +0.48 Hz, which is +0.48 Hz / 32768 Hz * 1'000'000 = +14.648 ppm. The Offset value in steps is then calculated as follows: +14.648 ppm / 0.9537 ppm = +15.36, the rounded integral part is 15 (the offset correction is -15 steps). The unsigned EEOffset value is then: 512 15 = +497. In binary, EEOffset = 111110001.
- If 32767.52 Hz is measured when the 32.768 kHz clock is selected, the offset is -0.48 Hz, which is -0.48 Hz / 32768 Hz * 1'000'000 = -14.648 ppm. The Offset value in steps is then calculated as follows: -14.648 ppm / 0.9537 ppm = -15.36, the rounded integral part is -15 (the offset correction is +15 steps). The EEOffset value is then: (-15) = +15. In binary, EEOffset = 000001111.

7.16.2. VERIFICATION OF THE CORRECTED TIME ACCURACY

The offset correction can be verified by the following process:

- 1. Enter the calculated EEOffset value (see **EEOFFSET Value Determination**).
- 2. Select the 1 Hz frequency on the FOUT pin (if another frequency is selected the following calculations have to be adapted).
- 3. Measure every period during one compensation period of 32 seconds at FOUT pin.
- 4. Calculate the average frequency Fmeas_aver in Hz.
- 5. Compute the new achieved offset value in ppm: POffset = ((Fmeas_aver 1) / 1 * 1'000'000)

7.17. UNIX TIME COUNTER

The UNIX Time counter is a 32-bit counter, unsigned integer, which rolls over to 00000000h when reaching the value FFFFFFFh. The 4 bytes are fully readable and writable. The counter source clock is the digitally tuned 1 Hz clock frequency of the prescaler.

After writing the required time value into the UNIX Time registers, the write access can be synchronized by the RESET bit function. When 1 is written to the RESET bit in control 2 register, the associated I²C stop condition will synchronize the 1 Hz counter clock to the desired accurate time. The RESET bit is then automatically cleared. The first 1 Hz period after synchronization will be 0 to 244 µs shorter than 1 second. The 32-bit counter value itself is not changed at the moment when 1 is written to the RESET bit.

When reading the counter, the current value is returned. Since it is not possible to block the counter during read, it is recommended to read the four registers (UNIX Time 0 to UNIX Time 3) twice and to check for consistent results.

1 To monitor the synchronicity of the 1 Hz tick to an external clock source, the 1 Hz clock can be enabled on FOUT pin or on the interrupt output pin nINT. For both, the negative edge corresponds to the internal 1 Hz-tick.

- ² A new value is entered to the UNIX Time counter registers (UNIX Time 0 to UNIX Time 3). The I²C-Stop after writing only to the UNIX registers does not provoke a synchronization of the 1 Hz-tick.
- ^③ Writing 1 to the RESET bit for highly accurate time adjustment (synchronizing). The first 1 Hz period after synchronization will be 0 to 244 μs shorter than 1 second. The RESET bit is automatically cleared. The synchronization can also be done by writing to the Seconds Register.

Figure 7-22 Unix Time Counter

7.18. RESET BIT FUNCTION

The RESET bit is used for a software-based accurate and safe starting of the time circuits.

When 1 is written to the RESET bit, the clock prescaler for 4096 Hz to 1Hz is reset and an eventual present memorized 1 Hz update is also reset. This bit is then automatically cleared. Because the upper two stages of the prescaler are not reset and the I²C interface is asynchronous, the next 1 Hz clock will be between (1 second – 244 µs) and 1 second. Resetting the prescaler will have an influence on the length of current clock period on all subsequent peripherals (clock and calendar, FOUT clock, timer clock, update timer clock, UNIX clock, EVI input filter).

The RESET bit function will not affect the FOUT of 32.768 kHz and 8192 Hz (see also FOUT Frequency Selection).

RESET bit functional diagram:

Figure 7-23 Reset bit Function

The clock and calendar can be set (in < 950 ms) and then synchronized by writing 1 to the RESET bit.

Setting the clock and calendar values using the RESET bit function:

- 1. Write the desired clock and calendar values to the registers (seconds, minutes, hours, weekday, date, month and year).
- 2. Write 1 to the RESET bit for a synchronized start of the time circuits (1 Hz tick). The RESET bit is automatically cleared.

7.19. USER PROGRAMMABLE PASSWORD

After a Power up and the first refreshment of ~66ms, the PW0 to PW3 registers are reset to 00h and the EEPWE (EEPROM 30h) and EEPW 0 to EEPW 3 values (EEPROM 31h to 34h) are copied from the EEPROM.

The first four Password registers (PW0 to PW3), in case of the use of the function (enabled by writing 255 into the EEPROM Password Enable register EEPWE), are used to write the 32-Bit Password necessary to be able to write in all writable registers (time and configuration registers). This 32-Bit Password is compared to the 32 bits stored in EEPROM Password registers EEPW 0 to EEPW 3 (see PASSWORD Registers, EEPROM Password Enable Register and EEPROM Password Registers).

Caution: The number of possible passwords is $2^{32} \approx 4.3 * 10^9 = 4.3$ billion.

7.19.1. ENABLING/DISABLING WRITE PROTECTION

If the write protection function is enabled by writing 255 in register EEPWE (EEPROM 30h), it remains possible to read all the registers except the EEPROM registers. If the function is not enabled, read and write are possible for all corresponding registers.

If the write protection function is enabled, it is necessary to first write the 32-Bit Password before any attempt to write in the RAM registers, and to read and write in the EEPROM registers.

Once the user is finished with the write access and subsequently the write protection is enabled again (by writing 255 in EEPROM register EEPWE), it is necessary to write an incorrect password (PW ≠ EEPW) into the Password registers PW0 to PW3 in order to write-protect the registers. See complete program sequences below and Flowchart.

Enable write protection:

- 1. Registers are Not write-protected (EEPWE ≠ 255)
- 2. Reference password is stored here (EEPW 0 to EEPW 3)
- 3. Disable automatic refresh (EERD = 1)
- 4. Enable password function (EEPWE = 255) (RAM)
- 5. Enter the correct password PW (PW = EEPW) to unlock write protection (PW0 to PW3)
- 6. Update EEPROM (all Configuration RAM → EEPROM) with EEcmd = 00h followed by 11h
- 7. Enable automatic refresh (EERD = 0)
- 8. Enter an incorrect password PW (PW ≠ EEPW) to (PW0 to PW3) to lock the device
- 9. Registers are Write-protected by password (EEPWE = 255)

Disable write protection:

- 1. Registers are write protected by password (EEPWE = 255)
- 2. Reference password is stored here (EEPW 0 to EEPW 3)
- 3. Enter the correct password PW (PW = EEPW) to unlock write protection (PW0 to PW3)
- 4. Disable automatic refresh (EERD = 1)
- 5. Disable password function (EEPWE ≠ 255) (RAM)
- 6. Update EEPROM (all Configuration RAM → EEPROM) with EEcmd = 00h followed by 11h
- 7. Enable automatic refresh (EERD = 0)
- 8. Registers are Not write-protected (EEPWE ≠ 255)

7.19.2. CHANGING PASSWORD

To code a new password, the user has to first enter the current (correct) password into the Password registers (PW0 to PW3) if the registers are write protected, and writing a value not equal to all 1 (value \neq 255) in the EEPWE register (EEPROM 30h) to unlock write protection, and then write the new one in the registers EEPW 0 to EEPW 3 (EEPROM 31h to 34h) and writing all 1 (value = 255) in the EEPWE register to enable password function. See complete program sequences below and Figure 7-24 User Programmable Password Flowchart.

Change password if password function is enabled (EEPWE = 255):

- 1. Registers are Write-protected by old password (EEPW 0 to EEPW 3)
- 2. Enter old password PW (PW = EEPW) to unlock write protection (PW0 to PW3)
- 3. Disable automatic refresh (EERD = 1)
- 4. Disable password function (EEPWE ≠ 255)
- 5. Define a new password EEPW (EEPW 0 to EEPW 3) (RAM), and edit other configuration settings (RAM)
- 6. Enable the password function (EEPWE = 255) (RAM)
- 7. Enter correct password PW (PW = EEPW) to unlock write protection (PW0 to PW3)
- 8. Update EEPROM (all Configuration RAM → EEPROM) with EEcmd = 00h followed by 11h
- 9. Enable automatic refresh (EERD = 0)
- 10. Enter an incorrect password PW (PW ≠ EEPW) to (PW0 to PW3) to lock the device
- 11. Registers are Write-protected by new password (EEPW 0 to EEPW 3)

Change password if password function is disabled (EEPWE ≠ 255):

- 1. Old password is stored here (EEPW 0 to EEPW 3)
- 2. Disable automatic refresh (EERD = 1)
- 3. Define a new password EEPW (EEPW 0 to EEPW 3) (RAM), and edit other configuration settings (RAM)
- 4. Update EEPROM (all Configuration RAM → EEPROM) with EEcmd = 00h followed by 11h
- 5. Enable automatic refresh (EERD = 0)
- 6. New password is stored here (EEPW 0 to EEPW 3)

7.19.3. FLOWCHART

The following Flowchart describes the programming of the enabling and disabling of the register write protection by user password and the changing of the user password if write protection is enabled or disabled.

User programmable password for register write protection:

Figure 7-24 User Programmable Password Flowchart

7.20. I²C INTERFACE

The I²C interface is for bidirectional, two-line communication between different ICs or modules. The EM3028 is accessed at addresses A4h/A5h, and supports Fast Mode (up to 400 kHz). The I²C interface consists of two lines: one bi-directional data line (SDA) and one clock line (SCL). Both lines are connected to a positive supply via pull-up resistors. Data transfer is initiated only when the interface is not busy.

7.20.1. BIT TRANSFER

One data bit is transferred during each clock pulse. The data on the SDA line remains stable during the HIGH period of the clock pulse, as changes in the data line at this time are interpreted as a control signals. Data changes should be executed during the LOW period of the clock pulse (see Figure 7-25 I2C Bit Transfer).

Figure 7-25 I²C Bit Transfer

7.20.2. START AND STOP CONDITIONS

Both data and clock lines remain HIGH when the bus is not busy. A HIGH-to-LOW transition of the data line, while the clock is HIGH, is defined as the START condition (S). A LOW-to-HIGH transition of the data line, while the clock is HIGH, is defined as the STOP condition (P) (see Figure 7-26 I2C Start and Stop Conditions).

Definition of START and STOP conditions:

Figure 7-26 I²C Start and Stop Conditions

A START condition which occurs after a previous START but before a STOP is called a Repeated START condition, and functions exactly like a normal STOP followed by a normal START.

Caution:

When communicating with the EM3028, the series of operations from transmitting the START condition to transmitting the STOP condition should occur within **950 ms**.

If this series of operations requires **950 ms or longer**, the I²C bus interface will be automatically cleared and set to standby mode by the bus timeout function of the EM3028. Note with caution that both write and read operations are invalid for communications that occur during or after this auto clearing operation (when the read operation is invalid, all data that is read has a value of FFh).

Restarting of communications begins with transfer of the START condition again.

7.20.3. DATA VALID

After a START condition, SDA is stable for the duration of the high period of SCL. The data on SDA may be changed during the low period of SCL. There is one clock pulse per bit of data. Each data transfer is initiated with a START condition and terminated with a STOP condition. The number of data bytes transferred between the START and STOP conditions is not limited (however, the transfer time must be no longer than 950 ms). The information is transmitted byte-wide and each receiver acknowledges with a ninth bit.

7.20.4. SYSTEM CONFIGURATION

Since multiple devices can be connected with the I²C-bus, all I²C-bus devices have a fixed and unique device number built-in to allow individual addressing of each device.

The device that controls the I²C-bus is the Master; the devices which are controlled by the Master are the Slaves. A device generating a message is a Transmitter; a device receiving a message is the Receiver. The EM3028 acts as a Slave-Receiver or Slave-Transmitter.

Before any data is transmitted on the I²C-bus, the device which should respond is addressed first. The addressing is always carried out with the first byte transmitted after the START procedure. The clock signal SCL is only an input signal, but the data signal SDA is a bidirectional line.

Figure 7-27 I²C System Configuration

7.20.5. ACKNOWLEDGE

The number of data bytes transferred between the START and STOP conditions from transmitter to receiver is unlimited (however, the transfer time must be no longer than 950 ms). Each byte of eight bits is followed by an acknowledge cycle.

- A slave receiver, which is addressed, must generate an acknowledge cycle after the reception of each byte.
- Also a master receiver must generate an acknowledge cycle after the reception of each byte that has been clocked out of the slave transmitter.
- The device that acknowledges must pull-down the SDA line during the acknowledge clock pulse, so that the SDA line is stable LOW during the HIGH period of the acknowledge-related clock pulse (set-up and hold times must be taken into consideration).
- A master receiver must signal an end of data to the transmitter by not generating an acknowledge cycle on the last byte that has been clocked out of the slave. In this event the transmitter must leave the data line HIGH to enable the master to generate a STOP condition.

Figure 7-28 I²C Acknowledge

7.20.6. SLAVE ADDRESS

On the I^2C -bus the 7-bit slave address 1010010b is reserved for the EM3028. The entire I^2C -bus slave address byte is shown in the following table.

Slave address							R/W	
Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Transfer data
1	0	1	0	0	1	0	1(R)	A5h (read)
'	U	l	0	0			0 (W)	A4h (write)

After a START condition, the I²C slave address has to be sent to the EM3028 device. The R/\overline{W} bit defines the direction of the following single or multiple byte data transfer. The 7-bit address is transmitted MSB first. If this address is 1010010b, the EM3028 is selected, the eighth bit indicates a read ($R/\overline{W} = 1$) or a write ($R/\overline{W} = 0$) operation (results in A5h or A4h) and the EM3028 supplies the ACK. The EM3028 ignores all other address values and does not respond with an ACK.

In the write operation, a data transfer is terminated by sending either the STOP condition or the START condition of the next data transfer.

7.20.7. WRITE OPERATION

Master transmits to Slave-Receiver at specified address. The Register Address is an 8-bit value that defines which register is to be accessed next. After writing one byte, the Register Address is automatically incremented by 1.

Master writes to slave EM3028 at specific address:

- 1) Master sends out the START condition.
- 2) Master sends out Slave Address, A4h for the EM3028; the R/\overline{W} bit is a 0 indicating a write operation.
- 3) Acknowledgement from EM3028.
- 4) Master sends out the Register Address to EM3028.
- 5) Acknowledgement from EM3028.
- 6) Master sends out the Data to write to the specified address in step 4).
- 7) Acknowledgement from EM3028.
- 8) Steps 6) and 7) can be repeated if necessary. The address is automatically incremented in the EM3028.
- 9) Master sends out the STOP Condition.

Figure 7-29 I²C Write Operation

7.20.8. READ OPERATION AT SPECIFIC ADDRESS

Master reads data from slave EM3028 at specific address:

- 1) Master sends out the START condition.
- 2) Master sends out Slave Address, A4h for the EM3028; the R/\overline{W} bit is a 0 indicating a write operation.
- 3) Acknowledgement from EM3028.
- 4) Master sends out the Register Address to EM3028.
- 5) Acknowledgement from EM3028.
- 6) Master sends out the Repeated START condition (or STOP condition followed by START condition)
- 7) Master sends out Slave Address, A5h for the EM3028; the R/\overline{W} bit is a 1 indicating a read operation.
- 8)Acknowledgement from EM3028.
 - At this point, the Master becomes a Receiver and the Slave becomes the Transmitter.
- 9) The Slave sends out the Data from the Register Address specified in step 4).
- 10) Acknowledgement from Master.
- 11) Steps 9) and 10) can be repeated if necessary. The address is automatically incremented in the EM3028.
- 12) The Master, addressed as Receiver, can stop data transmission by not generating an acknowledge on the last byte that has been sent from the Slave-Transmitter. In this event, the Slave-Transmitter must leave the data line HIGH to enable the Master to generate a STOP condition.
- 13) Master sends out the STOP condition.

Figure 7-30 I²C Master reads data from slave EM3028 at specific address

7.20.9. READ OPERATION

Master reads data from slave EM3028 immediately after first byte:

- 1) Master sends out the START condition.
- 2) Master sends out Slave Address, A5h for the EM3028; the R/\overline{W} bit is a 1 indicating a read operation.
- 3) Acknowledgement from EM3028.
- At this point, the Master becomes a Receiver and the Slave becomes the Transmitter.
- 4) The EM3028 sends out the Data from the last accessed Register Address incremented by 1.
- 5) Acknowledgement from Master.
- 6) Steps 4) and 5) can be repeated if necessary. The address is automatically incremented in the EM3028.
- 7) The Master, addressed as Receiver, can stop data transmission by not generating an acknowledge on the last byte that has been sent from the Slave-Transmitter. In this event, the Slave-Transmitter must leave the data line HIGH to enable the Master to generate a STOP condition.
- 8) Master sends out the STOP condition.

Figure 7-31 I²C Master reads data from slave EM3028 immediately after first byte

7.20.10. I²C-BUS IN SWITCHOVER CONDITION

To save power when the EM3028 is in VBACKUP Power state the bus I^2C -bus interface is automatically disabled (high impedance) and reset. Therefore the communication via I^2C interface should be terminated before the supply is switched from V_{DD} to V_{BACKUP} . When the bus communication is not terminated in a proper way, the time counters get corrupted.

If the I²C communication was terminated uncontrolled, the I²C has to be reinitialized by sending a STOP followed by a START after the device switched back from VBACKUP Power state to VDD Power state.

8. TYPICAL APPLICATION

8.1. OPERATING EM3028 WITH BACKUP SUPPLY VOLTAGE

- Low-cost MLCC (*) ceramic capacitor, supercapacitor (e.g. 1 farad), primary battery or secondary battery LMR (respect manufacturer specifications for constant charging voltage). When Lithium Battery is used, it is recommended to insert a protection resistor of 100 1000 Ω. to limit battery current and to prevent damage in case of soldering issues causing short between supply pins.
- $\stackrel{ ext{(2)}}{}$ For V_{DD} and V_{BACKUP} a 100 nF decoupling capacitor is recommended close to the device.
- When operating the EM3028 with either Supercap or Lithium Battery as Backup Supply, the nINT signal also works when the device operates on VBACKUP supply voltage. Therefore it is recommended to tie the nINT signal pull-up resistor to VBACKUP.
- 1 Interface lines SCL, SDA are open drain and require pull-up resistors to VDD.
- FOUT offers the selectable frequencies 32.768 kHz (default), 8192 Hz, 1024 Hz, 64 Hz, 32 Hz or 1 Hz, or the predefined periodic countdown timer interrupt for application use. If not used, it is recommended to disable FOUT for optimized current consumption (CLKOE = 0).

Figure 8-1 Example of Application

Component	Symbol	Value
CM7V-T1A	Crystal	32768Hz
Super capacitor	CBACKUP	1 F
Decoupling capacitor	C_D	100 nF
Pullup resistor	RPULLUP	10kΩ
•		

Table 64 Component list

8.2. CRYSTAL LAYOUT GUIDELINE

Since the crystal inputs have very high impedance and the EM3028 is Extreme Low Power, only 40nA, the leads to the crystal act like very good antenna, coupling high-frequency signals from the rest of the system. If a signal is coupled onto the crystal pins, it can either cancel out or add pulses. Since most of the signals on a board are at a much higher frequency than the 32.768 kHz crystal, it is more likely to add pulses where none are wanted. The following measures are essential for optimizing the configuration:

- It is important to place the EM3028 and crystal as close as possible to the Xtal_in and Xtal_out pins. Keeping the trace lengths between the crystal and RTC as small as possible reduces the probability of noise coupling by reducing the length of the antenna. Keeping the trace lengths small also decreases the amount of stray capacitance.
- Place a guard ring (connected to ground) around the crystal. This helps isolate the crystal from noise coupled from adjacent signals.
- Do not place any signal as FOUT, EVI, nINT, SCL, SDA or power lines close to the crystal oscillation circuit and Xtal_in, Xtal_out pin
- Ensure that no signals on other PCB layers run directly below the crystal or below the traces to the Xtal_in and Xtal_out pins. The more the crystal is isolated from other signals on the board, the less likely it is that noise is coupled into the crystal.
